SECTION 1

INTRODUCTION

This work plan was prepared by Parsons Engineering Science, Inc. (Parsons ES), formerly Engineering Science, Inc. (ES), and presents the scope of work required for the collection of data necessary to conduct a treatability study (TS) for the intrinsic remediation of groundwater contaminated with petroleum hydrocarbons and chlorinated aliphatic hydrocarbons (CAHs) at the Priority-One Site Fire Training Area 01 (FT-1) located at Fairchild Air Force Base (AFB), 12 miles west of Spokane, Washington (the Base). The record-of-decision (ROD) for FT-1 specifies the use of air sparging to remediate volatile organic compounds (VOCs) in site groundwater. Therefore, this TS will assess naturally occurring contaminant attenuation processes for groundwater and evaluate how these processes will operate in conjunction with the future air sparging system. This work plan is oriented toward the collection of hydrogeologic data to be used as input into groundwater flow and solute transport models to evaluate intrinsic remediation for restoration of groundwater contaminated with benzene, toluene, ethylbenzene, xylenes (BTEX), and CAHs.

As used in this report, the term "intrinsic remediation" refers to a management strategy that relies on natural attenuation mechanisms to remediate contaminants dissolved in groundwater and to control the potential for receptor exposure to siterelated contaminants in the subsurface. "Natural attenuation" refers to the actual physical, chemical, and biological processes that facilitate intrinsic remediation. Mechanisms for natural attenuation of BTEX and CAHs include advection, dispersion, dilution from recharge, sorption, volatilization, and biodegradation. processes, biodegradation is the only mechanism working to transform contaminants Intrinsic bioremediation occurs when indigenous into innocuous byproducts. microorganisms work to bring about a reduction in the total mass of contamination in Patterns and rates of intrinsic the subsurface without the addition of nutrients. remediation can vary markedly from site to site depending on governing physical and chemical processes.

As part of the TS, the contaminant fate and transport modeling effort will have two primary objectives: 1) predict the future extent and concentration of dissolved contaminant plumes by modeling the effects of advection, dispersion, sorption, and biodegradation in conjunction with an air sparging system; and 2) assess the possible exposure of potential downgradient receptors to contaminant concentrations that exceed levels intended to be protective of human health and the environment. The modeling efforts for the FT-1 site at Fairchild AFB will involve completion of several tasks, which are described in the following sections.

This work plan was developed following discussions among representatives from the Air Force Center for Environmental Excellence (AFCEE), the 92nd Civil Engineering Squadron--Environmental (92 CES/CEVR), and Parsons ES at a meeting held at the Base on July 11, 1995, to discuss the statement of work (SOW) for this project, and on a review of existing site characterization data. All field work will follow the health and safety procedures presented in the program *Health and Safety Plan for Bioplume II Modeling Initiative* (ES, 1993), and the site-specific addendum to the program Health and Safety Plan. This work plan was prepared for AFCEE and 92 CES/CEVR.

1.1 SCOPE OF CURRENT WORK PLAN

The ultimate objective of the work described herein is to provide a TS for intrinsic remediation of groundwater contamination at FT-1 in conjunction with the RODspecified air sparging system. However, this project is part of a larger, broad-based initiative being conducted by AFCEE in conjunction with the US Environmental Protection Agency (USEPA) and Parsons ES to document the biodegradation and resulting attenuation of fuel hydrocarbons and solvents dissolved in groundwater, and to model this degradation using numerical and analytical groundwater model codes. For this reason, the work described in this work plan is directed toward the collection of data in support of this initiative. This work plan describes the site characterization activities to be performed by personnel from Parsons ES and the USEPA National Risk Management Research Laboratory (NRMRL) Subsurface Protection and Remediation Division, formerly the USEPA Robert S. Kerr Environmental Research Laboratory, in support of the TS and the groundwater modeling effort. Field activities will be performed to determine if mobile and residual light nonaqueous-phase liquid (LNAPL) exists at the site and to determine the extent of LNAPL and dissolved contamination. The data collected during the TS will be used along with data from previous investigations to supplement the characterization of contamination at the site, and as input for the groundwater flow and solute transport models to make predictions of the future concentrations and extent of contamination.

Site characterization activities in support of the TS will include: 1) determination of preferential contaminant migration and potential receptor exposure pathways; 2) soil sampling using the Geoprobe® direct-push technology; 3) groundwater monitoring point placement; 4) groundwater sampling; and 5) aquifer testing. The materials and methodologies to accomplish these activities are described herein. Previously reported site-specific data and data collected during the supplemental site characterization activities described in this work plan will be used as input for the groundwater flow and solute transport models. Where site-specific data are not available, conservative values for the types of aquifer materials present at the site will be obtained from widely accepted published literature and used for model input. Sensitivity analyses will be conducted for the parameters that are known to have the greatest influence on the model results, and where possible, the model will be calibrated using historical site data.

This work plan consists of six sections, including this introduction. Section 2 presents a review of available previously reported, site-specific data and a preliminary conceptual hydrogeologic model for the site. Section 3 describes the proposed sampling strategy and procedures to be used for the collection of additional site characterization data. Section 4 describes the TS report format. Section 5 describes

the quality assurance/quality control (QA/QC) measures to be used during this project. Section 6 contains the references used in preparing this document. There are two appendices to this work plan. Appendix A contains a listing of containers, preservatives, packaging, and shipping requirements for soil and groundwater samples. Appendix B contains summary site data, including available well logs and summaries of historical soil and groundwater analytical data from previous field investigation work.

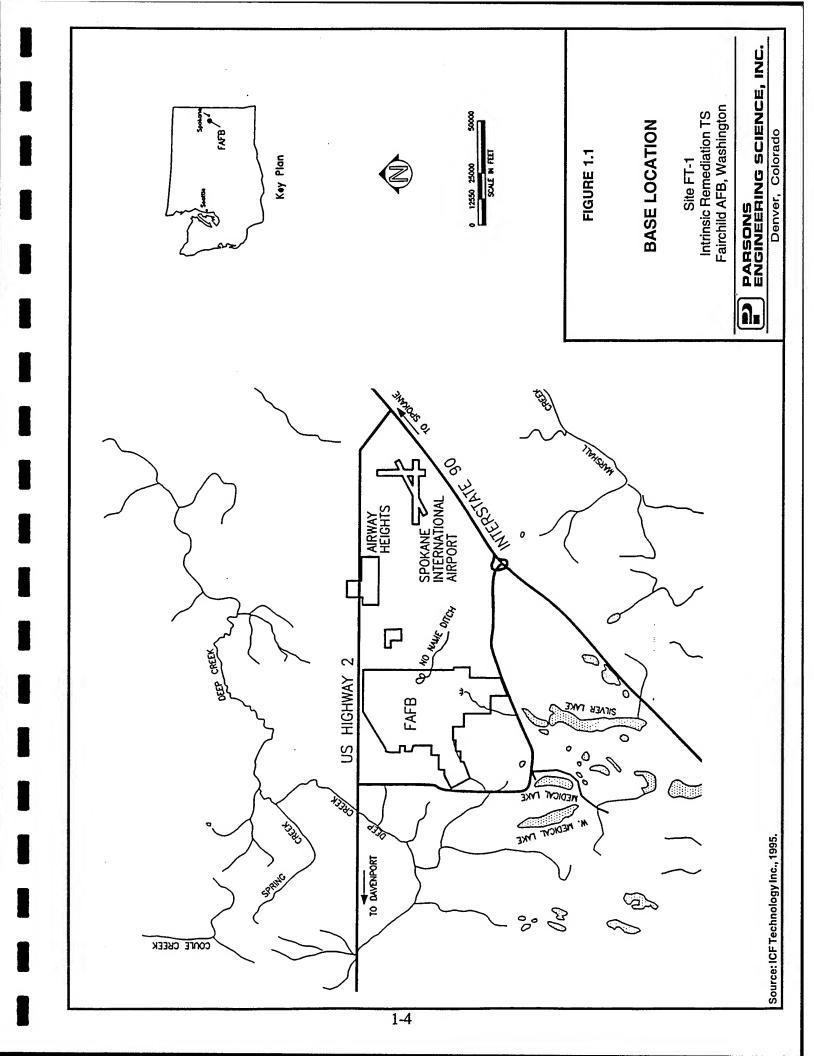

1.2 BACKGROUND

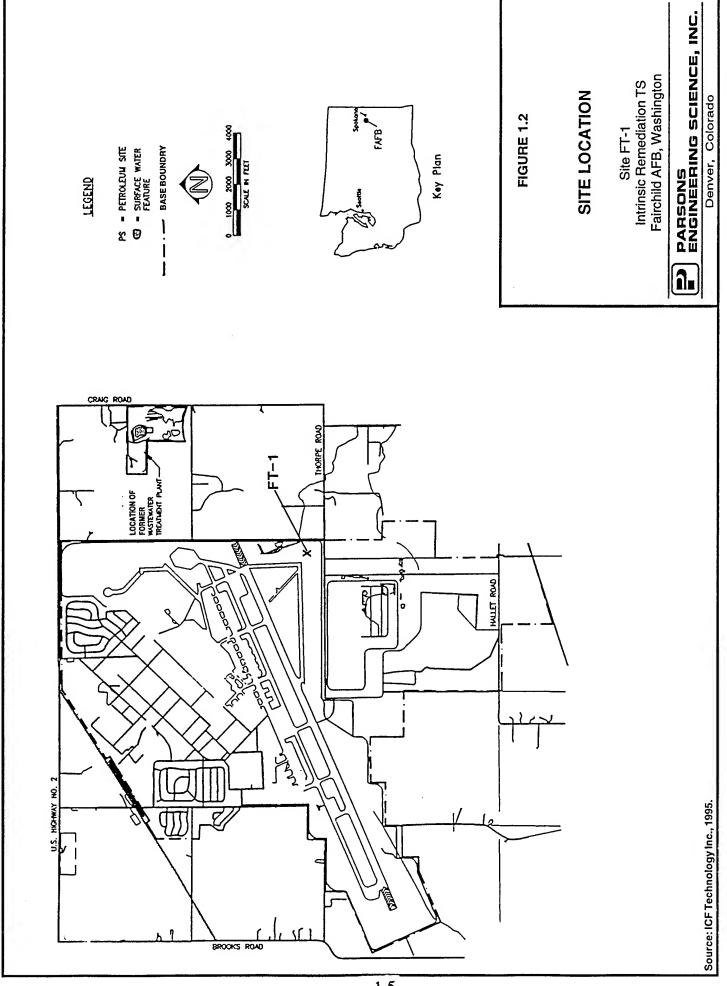

Fairchild AFB occupies an area of approximately 4,300 acres 12 miles west of Spokane, Washington (Figure 1.1). The Base is divided roughly in half by the main northeast/southwest runway (Figure 1.2). Aircraft operational facilities, approximately 1,600 Base housing units, an elementary school, a hospital, and support facilities for the tenants housed on-Base lie north of the runway. The air traffic control tower, weapons storage area, and survival training school lie to the south of the runway [Halliburton NUS (HNUS), 1993a].

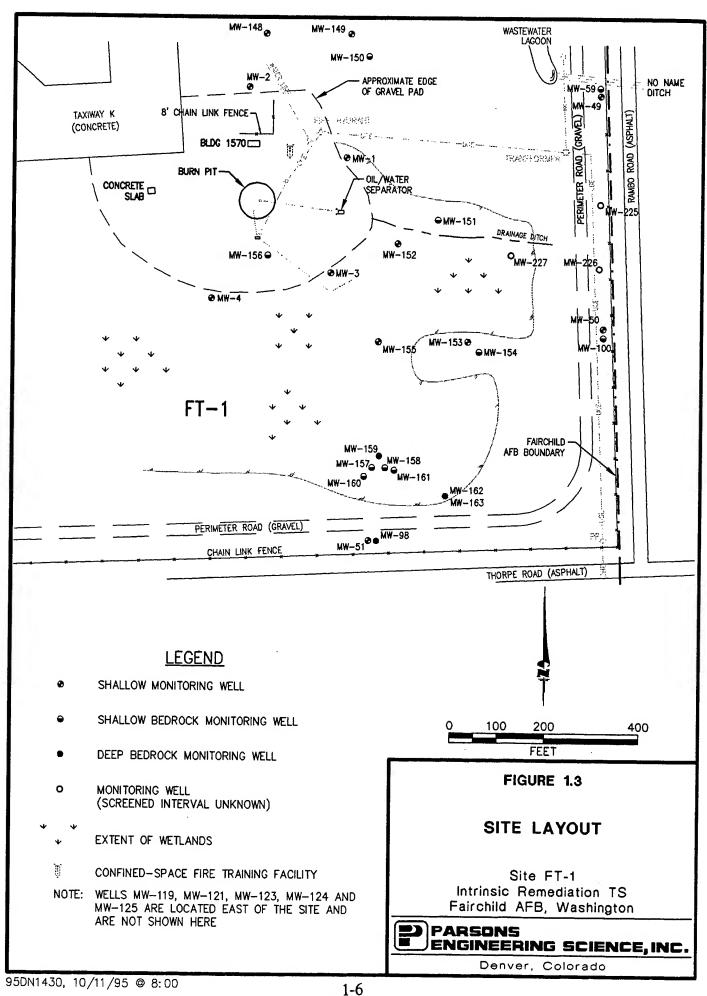

The Base was established in 1942 as an Army repair depot and transferred to the Strategic Air Command (SAC) in 1947. In 1992, Base control was transferred to the Air Combat Command (ACC). Currently, the Base is operated by the Air Mobility Command (AMC) and serves as host to the 92nd Air Refueling Wing. The Base also is the current home of the 141st Air Refueling Wing of the Washington Air National Guard (WANG), aircraft operational facilities, a weapons storage area, and a survival training school. Base operations employ approximately 5,000 civilian and military personnel (ES, 1994a).

Site FT-1 is a former fire training area located near the eastern property boundary of the Base between Taxiway 10 and Perimeter Road (Figure 1.3). Surface features at the site include a concrete fire training building (Building 1570), a subsurface confinedspace-entry training vault, and a concrete slab. A large gravel pad surrounds all of these surface features. A lined fire pit is located immediately south of Building 1570 (Figure 1.3). The pit was constructed in 1970 using bermed gravel, and a mock aircraft is located in the center of the pit. Prior to 1970, fire training exercises were performed in an unlined pit formerly located immediately north of the current lined fire training pit, near Building 1570. A 4,000-gallon underground storage tank (UST) located east of Building 1570 was used to store fuels used in fire training exercises. Pressure tests performed on this tank in 1989 did not indicated the presence of potential Additionally, an oil/water separator is located within the gravel pad approximately 150 feet east of the current training pit. It was used to separate unburned fuels from water that remained in the training pit after training exercises were conducted. A poorly defined manmade ditch receives effluent from the oil/water separator and discharges in a wide, flat, marshy area where outfall infiltrates the ground surface (HNUS, 1993a).

Fire training exercises were conducted on a regular basis at FT-1 until operations were ceased in August 1991. Recent exercises consisted of filling the training pit with 2 to 3 inches of water and spraying approximately 300 gallons of uncontaminated fuel hydrocarbons over the top of the water. The fuel was then ignited and aqueous film-forming foam (AFFF) was applied to extinguish the fire. In recent exercises only uncontaminated fuels were used. However, during historical exercises, waste fuels and

other types of hazardous waste substances were used. The nature of these other wastes was not described in previous reports reviewed during the development of this work plan (HNUS, 1993a).

Investigations were initiated at FT-1 as a result of Installation Restoration Program (IRP) Phase 1 Record Search conclusions (JRB Associates, 1985). The presence of groundwater contamination was confirmed in the IRP Phase II Confirmations/Quantification study performed by Battelle Denver Operations (1989). Since that time, a remedial investigation (RI) has been completed by HNUS (1993), an analytical informal technical information report (ITIR) for long-term groundwater monitoring has been submitted by EA Engineering, Science, and Technology and Montgomery Watson Americas, Inc. (ES&T and MWA, 1995), and a remediation pilot study is currently being performed (ES, 1994b).

To date, soil contamination has been detected near the current fire training pit and near the outfall of the oil/water separator. Dissolved BTEX contamination also has been detected in groundwater samples collected near the current fire training pit. Additionally, dissolved CAH contamination has been detected at low concentrations, typically less than 5 micrograms per liter (μ g/L), in samples collected from groundwater underlying the site and as far as 5,500 feet downgradient from the site. Dissolved BTEX concentrations, have been measured at concentrations significantly higher than dissolved CAH concentrations, with total dissolved BTEX concentrations as high as 1,320 μ g/L measured in groundwater samples collected during previous investigations. The presence of mobile LNAPL (i.e., free product) or dense nonaqueous-phase liquid (DNAPL) has not been detected during previous site investigations.

SECTION 2

DATA REVIEW AND CONCEPTUAL MODEL DEVELOPMENT

Previously reported site-specific data were reviewed and used to develop a conceptual site model (CSM) for the groundwater flow and contaminant transport conditions at FT-1. The CSM guides the development of sampling locations and analytical data requirements needed to support the modeling efforts and to evaluate remediation technologies, including intrinsic remediation. Section 2.1 presents a synopsis of available site characterization data. Section 2.2 presents the preliminary conceptual groundwater flow and contaminant transport model that was developed based on these data.

2.1 DATA REVIEW

The following sections are based upon review of data from the following sources:

- IRP Remedial Investigation Report (HNUS, 1993a);
- IRP Record of Decision On-Base Priority One Operable Units (Sites SW-1, IS-1, OU-1 (PS-2, PS-6, AND PS-8), FT-1 AND WW-1) (HNUS, 1993b);
- IRP Remedial Design Work Plan for Fire Training Area FT-1, Fairchild AFB, Washington (ES, 1994a)
- IRP Baseline Data Bioventing and Air Sparging Treatability Test Letter Report, Site FT-1, Fire Training Facility, Fairchild AFB, Washington (Parsons ES, 1994b);
- Addendum to the IRP Baseline Data Bioventing and Air Sparging Treatability Test Letter Report Site FT-1, Fire Training Facility, Fairchild AFB, Washington (Parsons ES, 1995);
- Analytical ITIR: Long-Term Monitoring, April 1995 Sampling Craig Road Landfill and Priority Sites SQ-1, PS-2, PS-8, and FT-01 (ES&T and MWA, 1995); and
- Long-Term Monitoring Report For Priority 1 Sites SW-1 (LF-01), PS-2 (SS-18), and PS-8 (SS-26) at Fairchild AFB, Washington (ICF Technology, Inc., 1995).

Several other reports contain site information that may be useful during the development of fate and transport models. These documents, which were unavailable during the development of this work plan, include:

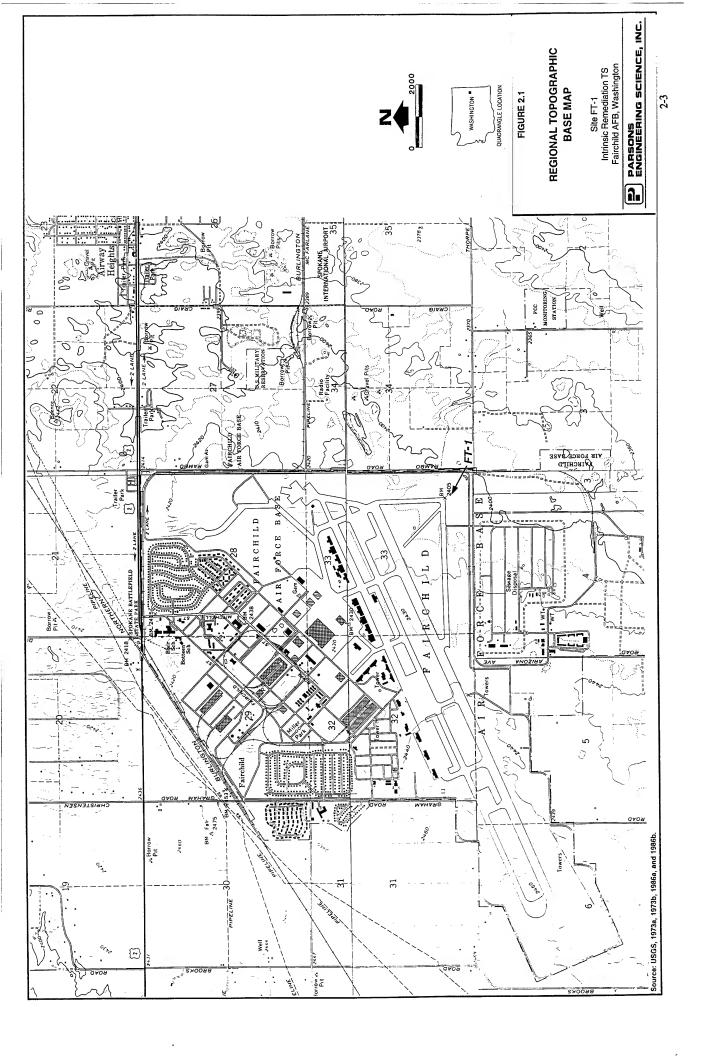

- Remedial Investigation/Feasibility Study (RI/FS) Site Characterization Summary Report Priority 1 Sites Fairchild AFB [Science Applications International Corporation (SAIC), 1990];
- IRP Phase II, Stage 1 Confirmation/Qualification, Stage 1 Fairchild AFB (Battelle Laboratories, 1985); and
- IRP Phase I Records Search, 92nd Bombardment Wing, Fairchild AFB (JRB Associates, 1985).

2.1.1 Topography, Surface Hydrology, and Climate

Fairchild AFB is located within the Columbia Basin in the northeastern corner of the 55,000-square-mile Columbia Plateau Physiographic Province (ICF Technology Inc., 1995). The Columbia Plateau is bordered by mountains and highlands on all side. The northern edge of the Plateau gives way to the Okanogan Highlands roughly 75 miles north of Fairchild AFB, while the eastern end of the Plateau is bordered by the Rocky Mountains, approximately 75 miles east of Fairchild AFB. The Plateau extends approximately 250 miles to the south and west of the Base. The Blue Mountains border the Plateau on the south, and the Cascade Mountains border the Plateau on the west. There is a watershed divide in the center of the Plateau that causes streams north of this divide to flow in a northerly direction, and streams south of the divide to flow in a southerly direction. The topography of the region was shaped by glacial flood waters that eroded the surface of the Columbia Plateau during the Pleistocene Epoch (approximately 22,000 years ago) (HNUS, 1993a). The surface topography of the Base and surrounding region is generally flat to gently rolling grasslands sloping slightly to the east-northeast. Ground surface elevations on the Base range from 2,400 to 2,460 feet above mean sea level (ft msl) (Figure 2.1).

Fairchild AFB is located in the northern half of the Columbia Plateau, north of the watershed divide. All surface water drainage in this region of the Columbia Plateau generally flows to the north or northwest (Flint, 1936). The Base is approximately 7 miles west-southwest of the Spokane River, which flows through the city of Spokane [US Geological Survey (USGS), 1973a, 1973b, 1986a, and 1986b]. Two other drainages in the vicinity of the Base are Deep Creek and Marshall Creek, located approximately 2 miles northwest and 8 miles southeast of the Base, respectively. These creeks flow northwest and join the Spokane River, which drains this region of the Plateau. Surface water on the Base is generally limited to precipitation runoff and intermittent flow in No Name Ditch near the eastern boundary of the Base just north of FT-1. Precipitation runoff is controlled within a series of manmade ditches. Reportedly, water collected in the ditch system does not leave Base property, and surface water either infiltrates the subsurface or evaporates (HNUS, 1993a).

At FT-1, storm precipitation is reported to infiltrate into the ground. A manmade drainage ditch extends approximately 300 feet eastward from the oil/water separator on the eastern edge of the training pit and terminates in a broad flat marshy area. The oil/water separator treated discharge generated during fire training exercises. Fire training exercises ceased at the site in 1991, and the oil/water separator is currently

inactive. Snowmelt runoff was observed in the ditch during the RI activities (HNUS, 1993a).

Fairchild AFB is surrounded by semi-arid grasslands common to this area of the Columbia Basin. The Base receives approximately 16 inches of rainfall during the warm dry summers, and 40 inches of snowfall during the cool, damp winter months. The prevailing wind direction in the region is to the northeast at an average speed of 8 miles per hour (ICF Technology, Inc., 1995). The average evapotranspiration rate for the region is reported at 12.8 inches per year (JRB Associates, 1985). Maximum infiltration rates usually occur during the early spring when snow melt runoff combines with precipitation while temperatures are still cool and evapotranspiration is low (HNUS, 1993a).

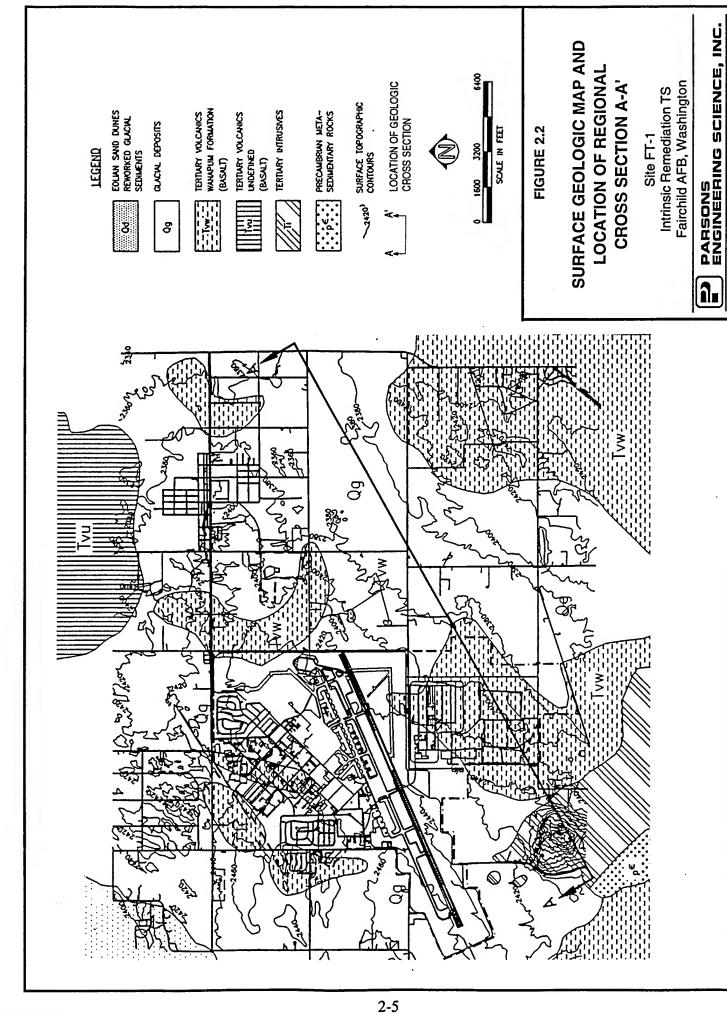

2.1.2 Overview of Geology and Hydrogeology

2.1.2.1 Regional Geology and Hydrogeology

The shallow subsurface geology at Fairchild AFB is a mixture of Quaternary sediments consisting of eolian, glacial, fluvial, lacustrine deposits (Figure 2.2). Flood waters from the glacial-era Missoula Lake scoured the basalt bedrock of this region of the Columbia Plateau. Coarse sediments were deposited during the early recession of flood waters, followed by finer sediments during the later stages of floodwater recession. The alluvium in the vicinity of the Base generally consists of fine-grained sediments deposited by receding glacial flood waters. Clays and silts are intermixed with sandy silts, clays, and gravels (HNUS, 1993a). Additionally, loess (windblown silt) deposits are interbedded in portions of the unconsolidated deposits. Unconsolidated deposits generally follow the slope of the underlying basalt bedrock (ICF Technology, Inc., 1995).

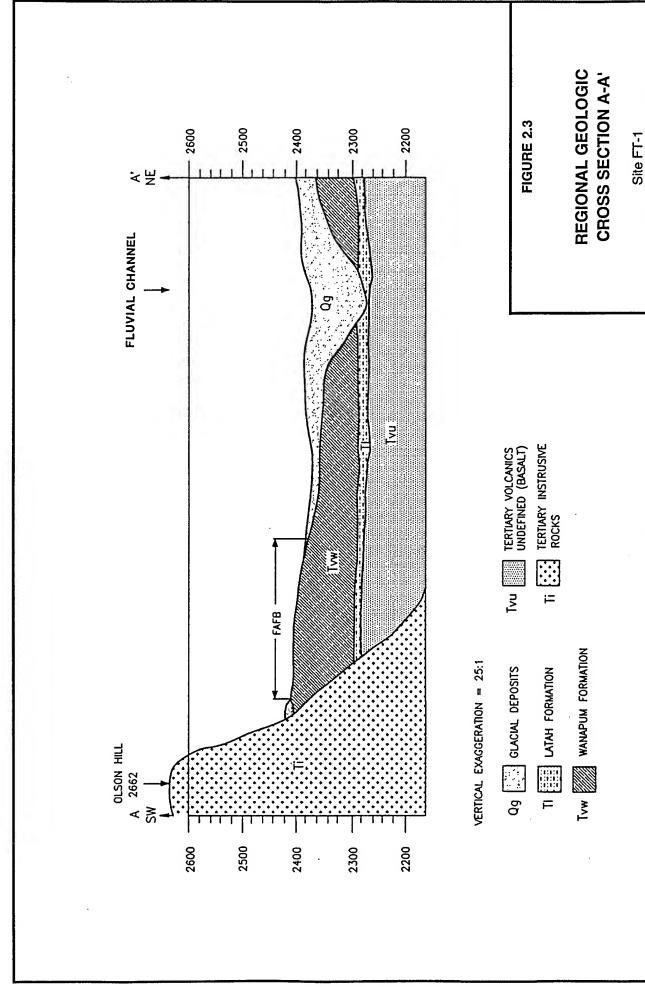

Bedrock in the vicinity of the Base is mostly Tertiary basalts of the Columbia River Basalts below Fairchild AFB are of the Wanampum Formation (HNUS, 1993a). The basalt flows in the region are interbedded with sedimentary clay and silt units of the of the Latah Formation. These layers were deposited when stream beds were isolated by the volcanic basalt flows (Cline, 1969). The Wanampum Basalt flow below the Base appears to be divided into an upper and lower flow sequence by an interbed of the Latah Formation (Figure 2.3). The upper basalt flow is 166 feet to 193 feet thick across the Base. The surface of the upper basalt flow is vesiculated, deeply fractured, and highly weathered in places. Just east of the Base the upper basalt layer was completely eroded away by the Missoula Lake flood waters. The middle of this flow contains few vesicles and fractures; the formation becomes more massive and The underlying Latah Formation deposits consist of an competent with depth. extensive silty claystone that ranges in thickness from 8.5 to 10 feet (HNUS, 1993a). Information on the geologic characteristics of the lower basalt flow was not available in the previous reports reviewed as part of this work plan; however, information on the lower basalt flow is not considered to be vital to the formation of the CSM for data collection to evaluate intrinsic remediation at FT-1.

Groundwater in the vicinity of the Base is encountered from 8 to 12 feet below ground surface (bgs) and is found in both the unconsolidated material and the

Denver, Colorado

Denver, Colorado

Intrinsic Remediation TS Fairchild AFB, Washington

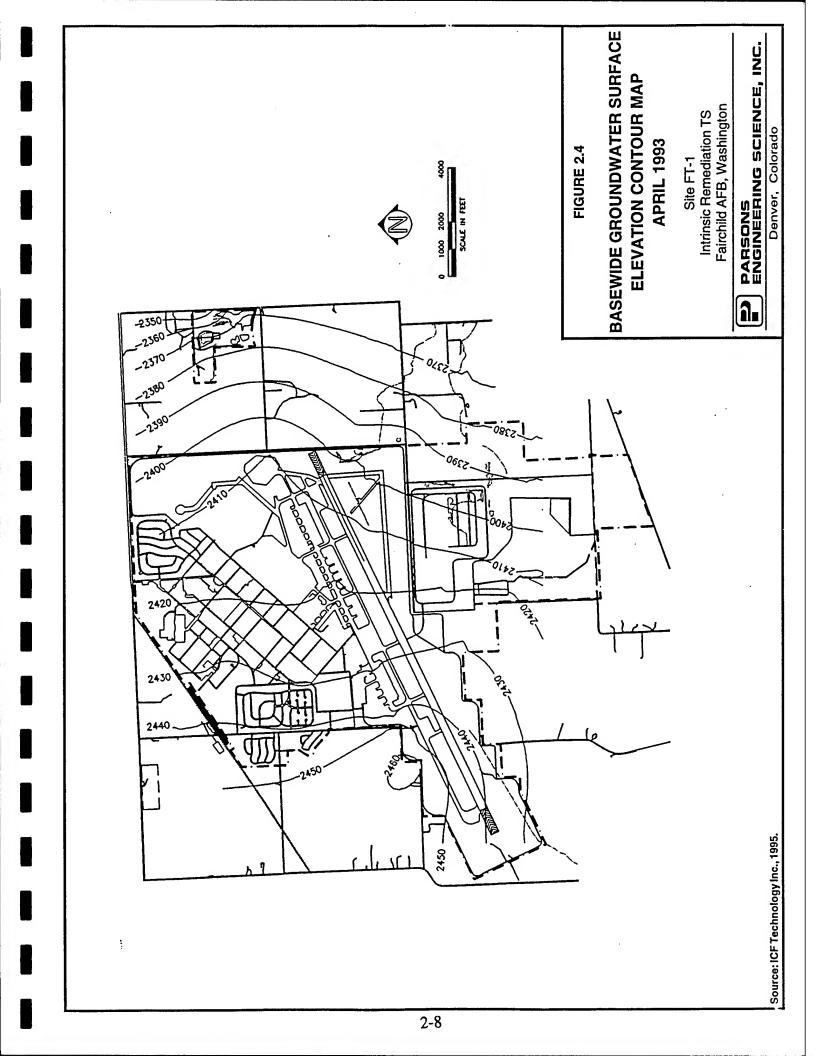

underlying basalt bedrock. Groundwater flow in the unconsolidated deposits is through intergranular pore space, while flow in the basalt is through interconnecting fractures (HNUS, 1993a). Flow across the Base is generally to the east and east-northeast, but local variations may result from local changes in bedrock topography (Figure 2.4). Groundwater in the unconsolidated material and shallow bedrock is generally unconfined, with some local semiconfined areas. The unconsolidated material and the shallow basalt are hydraulically connected by fractures, vesicles, and weathered zones. The middle region of the shallow basalt flow is more competent with less fracturing, and acts as an aquitard. The interbedded claystone between the basalt flows also acts as a confining layer (HNUS, 1993a).

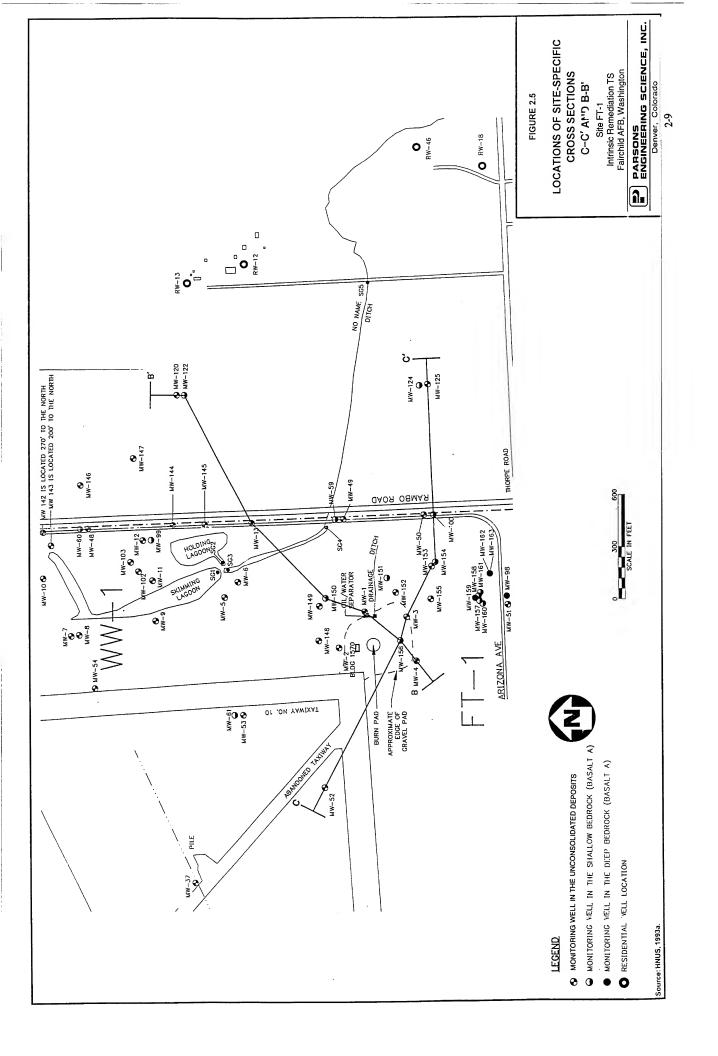

Recharge of the aquifer under the Base is expected to come from upgradient flow and surface runoff infiltration. Groundwater in the shallow aquifer in the vicinity of the Base is not known to be used as a drinking water supply. Neighborhoods to the east and northeast of the Base obtain domestic and agricultural water primarily from private wells which tap aquifers in the deeper basalt flows. The closest residential neighborhoods are roughly 1,800 feet east (downgradient) of the site. Base drinking water is primarily supplied from a Base-owned well field 10 miles northwest of the Base. Additionally, there is a water supply well located in the southern area of the Base. This well also produces water from the basalt aquifer and supplies roughly 10 percent of the Base's needs (HNUS, 1993a).

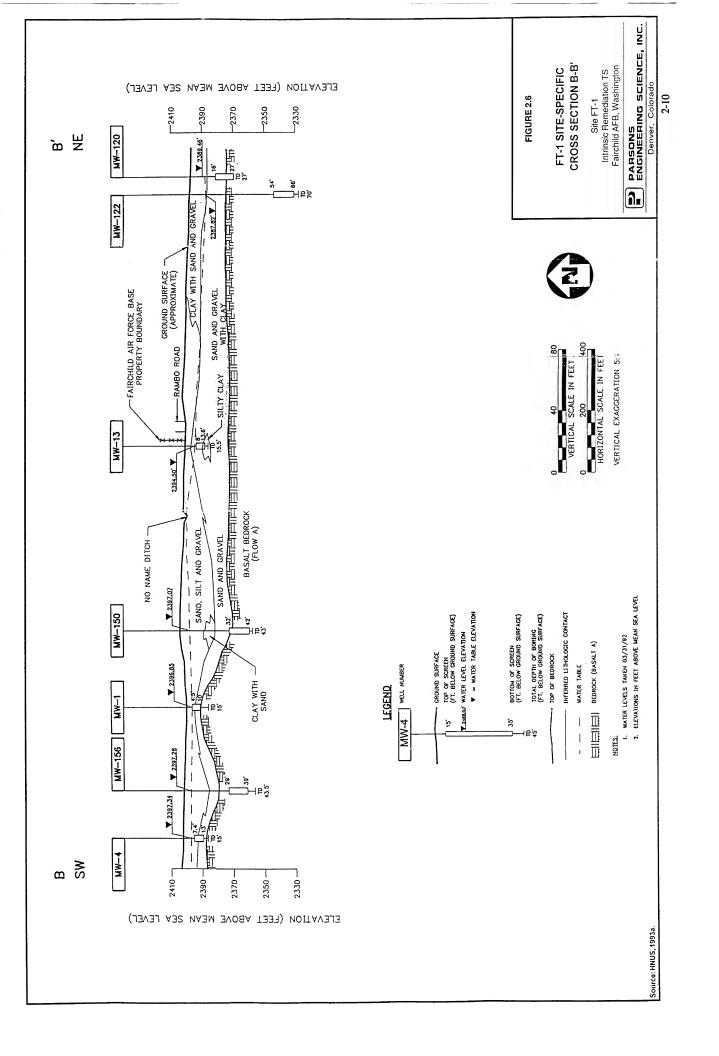

2.1.2.2 FT-1 Geology and Hydrology

Site geology and hydrogeology descriptions are summarized principally from descriptions provided in the RI (HNUS, 1993a). Surface soils at the site primarily consist of Cheney and Uhlig Series clayey silts, and the description of subsurface soils underlying FT-1 is relatively consistent with the regional geology described in Section 2.1.2.1. Unconsolidated material overlying the basalt bedrock ranges in thickness from 9 feet to 30 feet across the site. Shallow deposits at FT-1 are primarily silty clays and clayey silts with sands, while deeper unconsolidated material appears to be coarsergrained and consists of silty sands and gravels. Unconsolidated material overlies two distinct basalt flows that are separated by a Latah Formation sedimentary interbed. Geologic cross sections B-B' and C-C' depict the unconsolidated material and shallow regions of the upper basalt bedrock underlying the site. The locations of these cross sections are shown on Figure 2.5, with cross section A-A' presented on Figure 2.6 and cross section B-B' presented on Figure 2.7.

Geologic features of the shallow basalt flow, sedimentary interbed, and upper portion of the deeper basalt flow underlying FT-1 were investigated during the installation of a cored hole later completed as MW-159. Packer tests were performed at 10-foot intervals during the installation of this hole. Results of the packer testing performed at FT-1 are presented in Table 2.1. The shallow basalt flow is estimated to be 192 feet thick and to extend to a depth of 207 feet bgs. The upper 50 feet of the shallow basalt flow is described as being massive weathered basalt with small vesicles and slight to moderate fracturing. The middle portion of the upper basalt flow becomes more dense with fewer vesicles and hairline fractures existing from 65 to 180 feet bgs. From 180 feet to 205 feet bgs, the flow is described as relatively nonfractured and nonvesicular massive basalt. The bottom few feet of the upper basalt flow, near the

^{a'} The 214- to 216-foot interval was not tested to avoid bridging the Interbed A and Basalt B interface.

Latah interbed, becomes more vesicular. The Latah Formation interbed separating the upper and lower basalt flows is approximately 8.5 feet thick and extends from 207 feet bgs to 215.5 feet bgs. This interbed consists of silty claystone with deposits of organic material. The upper portion of the deep basalt flow is described as highly vesicular with a moderate to high number of fractures and minor weathering. Deeper portions of the lower basalt flow had not been investigated in reports reviewed during the development of this work plan.

There are currently 39 groundwater monitoring wells associated with FT-1, including 18 wells screened in the unconsolidated deposits and 18 wells screened in the basalt bedrock. Construction details for three monitoring wells, MW-225, MW-226, and MW-227, were not available in reports reviewed during the development of this work plan. Groundwater at the site resides in the Quaternary glacial deposits and in the underlying upper basalt bedrock. Available monitoring well construction details and select well level data are presented in Table 2.2. Figure 2.8 shows the groundwater surface for FT-1 in March 1992.

In the immediate vicinity of the site, groundwater flows to the east-southeast, which is consistent with the regional flow direction. Groundwater elevations measured in March 1992 indicate the average hydraulic gradient across FT-1 is approximately 0.002 foot per foot (ft/ft); however, the hydraulic gradient in the source area and immediately east of Rambo Road is somewhat steeper, at 0.007 ft/ft (Figure 2.8) (HNUS, 1993a). Fluctuations of up to 9 feet were observed in monitoring well data collected from February 1991 to April 1992 (HNUS, 1993a). Typically, groundwater elevations at Fairchild AFB are lower during August through November, and higher during April through July (ICF Technology, Inc., 1995).

Six unconsolidated deposits/shallow bedrock groundwater monitoring wells pairs (MW-49 and MW-59; MW-149 and MW-150; MW-50 and MW-100; MW-153 and MW-154; MW-157 and MW-158; and MW-53 and MW-61) were installed to investigate vertical hydraulic gradients and the vertical extent of contamination in groundwater underlying FT-1. Groundwater elevation data collected in 1991 and 1992 suggest downward vertical gradients of 0.006, 0.01, 0.006, and 0.0006 ft/ft for monitoring well pairs MW-49 and MW-59, MW-149 and MW-150, MW-50 and MW-100, and MW-157 and MW-158, respectively. Water elevations measured within the groundwater monitoring wells MW-154 and MW-153 did not indicate the presence of a vertical gradient near this pair (HNUS, 1993a). In 1992, the maximum downward vertical gradient was measured at 0.58 ft/ft between wells MW-53 and MW-61. Basalt bedrock well MW-61 exists in a high-yielding fracture zone. Because of the large differences in hydraulic heads between well MW-61 and the nearby unconsolidated deposit well and other site wells screened between 60 and 70 feet bgs in the basalt bedrock, it is believed that the fracture zone at MW-61 is hydraulically isolated from other site wells of similar or shallower depth.

Large differences in groundwater elevations were observed between all well pairs screened in the shallow bedrock and in the deeper regions of the upper basalt flow. In 1992, groundwater elevations measured in deep bedrock monitoring wells MW-159, MW-98, and MW-163 were 172 feet, 80 feet, and 169 feet lower than measurements collected from MW-51 the nearest shallow well. These differences appear to indicate

that groundwater in the unconsolidated deposits and the shallow bedrock is not in communication with groundwater in deeper regions of the bedrock. Generally, however, groundwater in the unconsolidated deposits and the shallow bedrock appears to be in hydraulic communication, with indications of a small downward hydraulic gradient.

Pumping tests were performed in the unconsolidated material monitoring wells MW-1 and MW-155, both of which are screened across gravely sand deposits. Drawdown was not observed during either test in the nearest observation wells MW-3 and MW-153, located approximately 170 feet and 187 feet from their respective pumping wells (Figure 2.5). A semilog analysis was used to estimate the hydraulic conductivities and transmissivities for the pumping tests performed at MW-1 and MW-155 (Theis, 1935). The hydraulic conductivities calculated from the pump test data are 418 feet per day (ft/day) at MW-1 and 37 ft/day at MW-155. Transmissivities were calculated at 2,410 square feet per day (ft²/day) and 214 ft²/day at wells MW-1 and MW-155, respectively (HNUS, 1993a). An additional pumping test was performed in the shallow bedrock well, MW-157. Drawdown was observed in wells MW-160 and MW-161 approximately 40 and 48 feet away from MW-157 (see Figure 2.5). The average hydraulic conductivity and average transmissivity calculated from drawdown data collected from the observation wells are 0.8 ft/day and 21.8 ft²/day, respectively. Pumping tests could not be performed in the deeper regions of the upper basalt flow because sufficient pumping rates could not be sustained in installed pumping wells (HNUS, 1993a).

2.1.3 Summary of Analytical Data for FT-1

2.1.3.1 Soil Sampling and Analytical Results

Historical soil sampling data are available for sampling events that took place in 1986, 1988, 1990, and 1994. In 1986, six soil samples were collected from boreholes B-1 through B-3 installed at FT-1. Two years later, 20 additional soil samples were collected during the installation of monitoring wells MW-49 through MW-53 and boreholes BH-1 through BH-5. In 1990, 33 additional soil samples were collected from 20 additional soil boreholes, 001 through 020. In 1994, ES (1994b) collected seven soil samples during the installation of four vapor monitoring point (VMPs) at FT-1 (Figure 2.9). At a minimum, soil samples collected during these sampling events were analyzed for BTEX, trichloroethene (TCE), cis-1,2-dichloroethene (cDCE), trans-1,2-dichloroethene (tDCE), vinyl chloride (VC), and total petroleum hydrocarbon (TPH) data. The ROD specifies that benzene is the primary contaminant of concern at the site (HNUS, 1993b); however, BTEX, TPH, and TCE-related contaminants are all of interest for the intrinsic remediation demonstration for shallow groundwater underlying FT-1. Soil samples collected during previous investigations were analyzed for additional contaminants; however, results reported for additional contaminants are not of primary importance for completion of this TS and are not summarized in this work plan. Table 2.3 summarizes BTEX and TPH results for all soil samples collected during these sampling efforts. CAH contamination has not been detected in site soils (ES, 1994b); therefore, results are not reported in Table 2.3. The approximate extent of soil BTEX and TPH contamination and the locations of all soil samples collected at FT-1 are shown in Figure 2.9. Isoconcentration lines have not been added

to Figure 2.9 because active *in situ* remedial efforts are currently treating these soils, and current soil data are not available.

The greatest BTEX and TPH contamination was detected in soil samples collected from the burn pit and the area south of the burn pit (Table 2.3). At FT-1, the highest soil concentrations of BTEX and TPH were detected in 1986 in borehole B-3 installed in the southern portion of the burn pit (Figure 2.9). The highest BTEX concentrations in the 1990 soil sampling effort were detected in the 4- to 6-foot bgs sample collected from borehole 010, south of the burn pit (HNUS, 1993a). BTEX and TPH also were detected in soil samples collected from the VMPs installed during the bioventing pilot test and located approximately 15 feet south of the burn pit (ES, 1994b).

A secondary region of soil contamination has been identified east of the burn pit. Samples collected in 1986 from soil boreholes B-1 and B-2, located approximately 200 and 250 feet east of the burn pit, respectively, had elevated BTEX concentrations (Table 2.3). A soil sample collected in 1988 from soil borehole BH-1, located approximately 400 feet east of the burn pit, also had elevated concentrations of soil contamination. Each of these boreholes is located immediately downstream and downgradient from the effluent outfall from the oil/water separator (Figure 2.9). Additionally, BTEX and TPH were detected in one composite sample collected from 019 along the eastern edge of the burn pit upgradient from the oil/water separator and in samples from 101 southwest of the pit, and 014 and 015 to the east along the ditch. In summary soil contamination at FT-1 has been identified along the southern and eastern edges of the burn pit and east of the oil/water separator.

2.1.3.2 Groundwater Sampling and Analytical Results

A total of 40 monitoring wells have been installed in the vicinity of FT-1. In 1988, five monitoring wells (MW-49, MW-50, MW-51, MW-52, and MW-53) were installed at FT-1. In 1991, 16 additional monitoring wells (MW-148 through MW-163) were installed at FT-1 (HNUS, 1993a). Although numerical well numbers suggest the sequence of installation of monitoring wells at FT-1, exact dates of installation and other construction details for the remaining 17 wells were not presented in previous reports reviewed during the development of this work plan.

Groundwater quality data reviewed during development of this work plan were collected during sampling events performed at FT-1 in 1986, 1987, 1989 (two sampling events), 1990, 1991 (three sampling events), 1993, and 1995. Concentrations of VOCs and TPH were measured in groundwater samples collected during all sampling events. Other analytical data collected during previous sampling events including total dissolved solids, total suspended solids, chemical oxygen demand, biological oxygen demand, total organic carbon (TOC), ammonia, common anions, and nitrate/nitrite data, will be useful for evaluating intrinsic remediation at FT-1, and efforts will be made to obtain this data (HNUS, 1993a). However, only analytical data for BTEX, TPH, TCE, and TCE breakdown products were available for inclusion in this work plan. Concentrations of dissolved BTEX, TPH, TCE, and TCE breakdown products measured in groundwater samples collected during previous investigations are summarized in Table 2.4. Benzene and total BTEX concentrations detected in

groundwater samples collected during the most recent 1995 sampling effort are presented in Figure 2.10. TCE and TCE-breakdown product detected during the 1995 sampling effort are presented in Figure 2.11.

Dissolved BTEX have repeatedly been identified in groundwater samples from shallow wells in the unconsolidated deposits southeast of the burn pit. Dissolved BTEX concentrations also have been detected at low concentrations in some bedrock wells southeast of the burn pit. Dissolved BTEX have not been detected in other regions of the site. Neither shallow nor bedrock wells are located within 100 feet of the burn pit. Comparison of BTEX groundwater data collected at FT-1 suggests that BTEX concentrations downgradient of the burn pit have increased with time. This trend is observed in groundwater results from monitoring wells MW-3 and MW-152. In 1995, a slight decline in the BTEX concentrations was observed at MW-3, the well closer to the burn pit. This decline may be the direct result of on-going bioventing and air sparging pilot tests, which were initiated in 1994, or it may be a statistical anomaly. Additional dissolved BTEX data are needed to fully characterize the areal extent of dissolved BTEX contamination and in order to more thoroughly understand the dynamics of the dissolved BTEX plume downgradient from the burn pit.

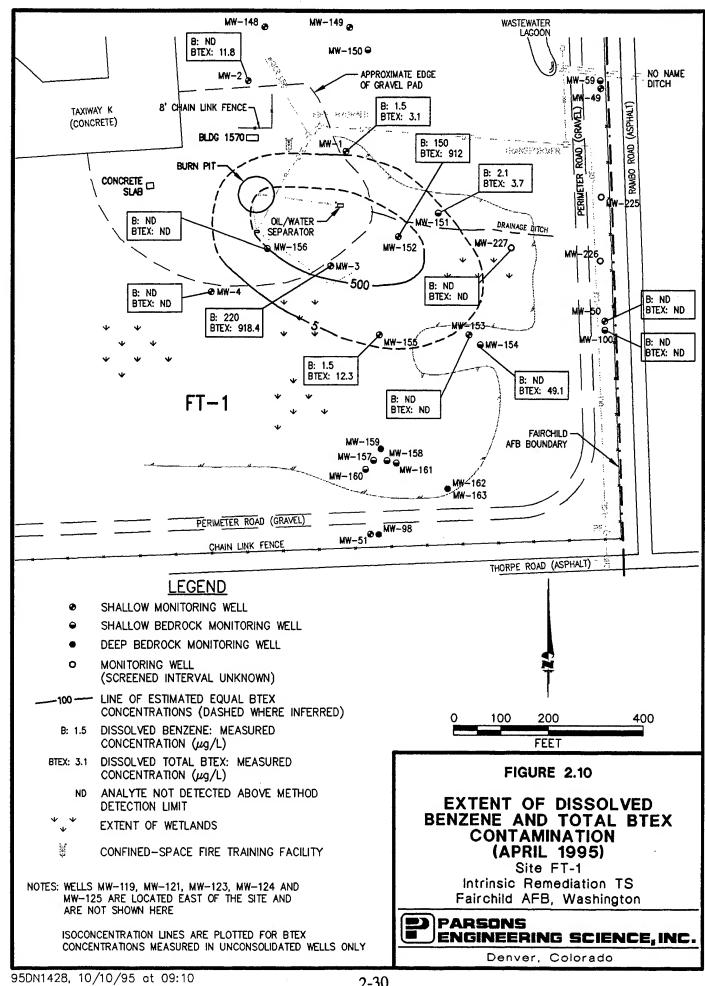

Low concentrations of TCE and related breakdown products have been detected consistently in three areas at the site: near the burn pit, along the eastern boundary of the Base near MW-50 and MW-100, and near the southern boundary of the Base near MW-51 (Figure 2.11 and Table 2.4). Concentrations of TCE and breakdown products measured throughout the site are relatively constant and low, equal to or less than 5 μ g/L. In the other regions of the site, the concentrations of TCE and breakdown products appear to be decreasing over time. TCE contamination also has been detected up to 1 mile downgradient from the site in surrounding residential wells, but all detected concentrations of TCE in groundwater samples collected from residential wells located immediately east-southeast of the site are below 1 μ g/L, as shown on Figure 2.12. (HNUS, 1993a).

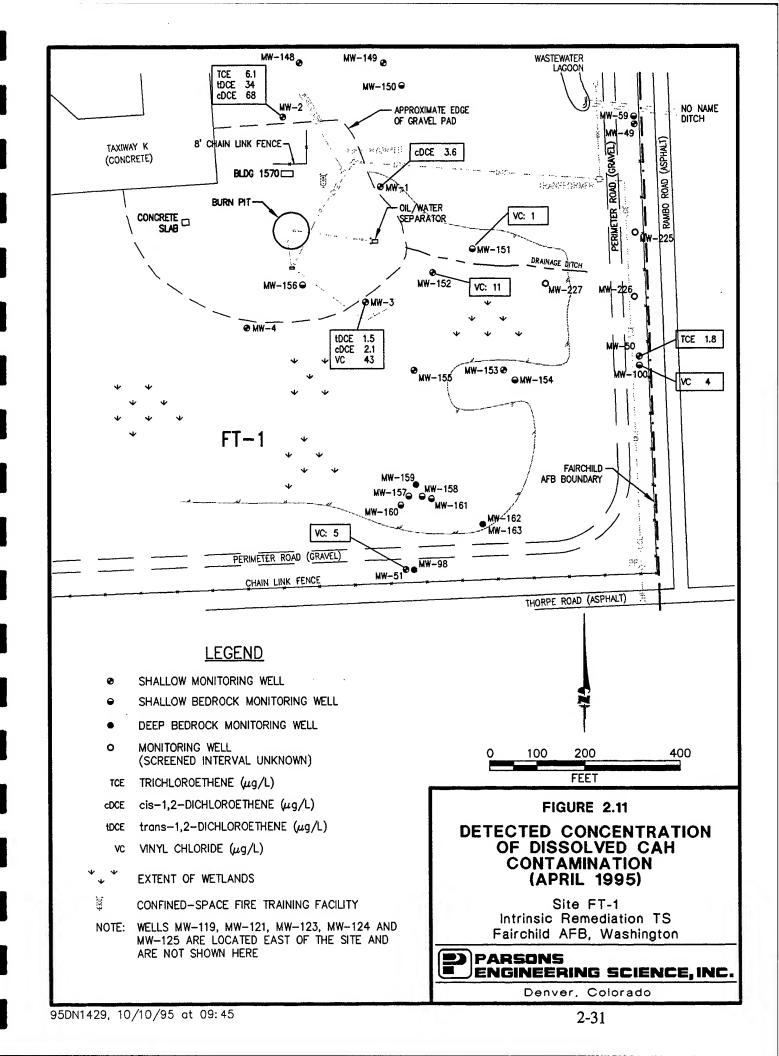

2.2 DEVELOPMENT OF CONCEPTUAL SITE MODEL

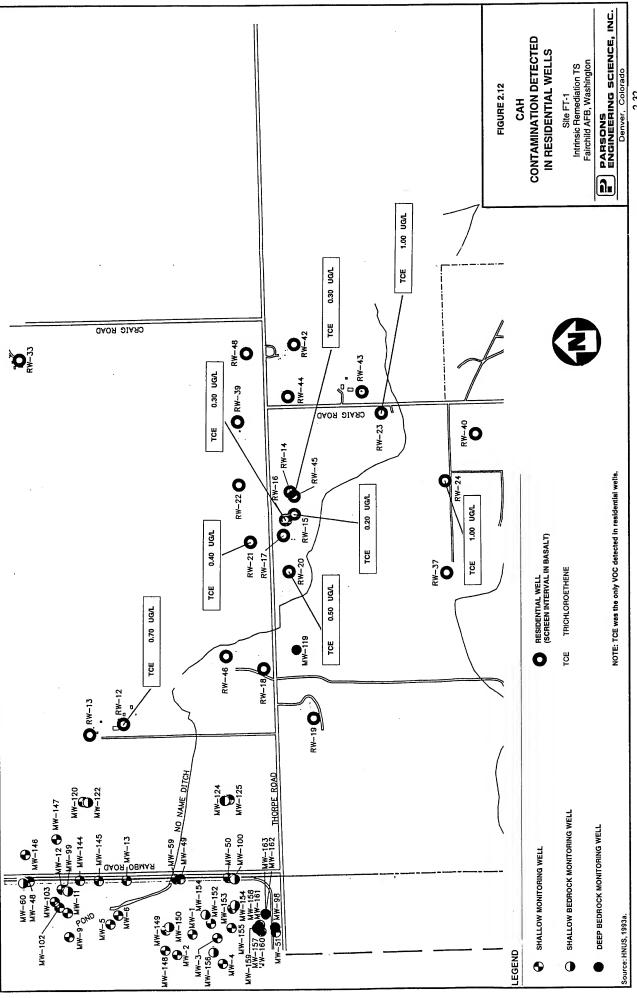

A CSM is a three-dimensional representation of a site's hydrogeologic system based on available geological, hydrological, climatological, and geochemical data. A CSM is developed to provide an understanding of the mechanisms controlling contaminant fate and transport and to identify additional data requirements. The model describes known and suspected sources of contamination, types of contamination, affected media, and contaminant migration pathways. The model also provides a foundation for formulating decisions regarding additional data collection activities and potential remedial actions. The CSM for FT-1 will be used to aid in selecting additional data collection points and to identify appropriate data needs for modeling and hydrocarbon degradation using groundwater flow and solute transport models.

Successful conceptual model development involves:

• Defining the problem to be solved;

- Integrating available data, including
 - Local geologic and topographic data,
 - Hydraulic data,
 - Site stratigraphic data,
 - Contaminant concentration and distribution data;
- Evaluating contaminant fate and transport characteristics;
- Identifying contaminant migration pathways;
- Identifying potential receptors and receptor exposure points; and
- Determining additional data requirements.

2.2.1 Intrinsic Remediation and Groundwater Flow and Solute Transport Models

After a site has been adequately characterized, fate and transport analyses can be performed to determine the potential for contaminant migration and whether any pathway for exposure of human or ecological receptors to site contaminants is complete or may be completed in the future. Groundwater flow and solute transport models have proven useful for predicting BTEX plume migration and contaminant attenuation by natural biodegradation. Analytical solute transport models and the Bioplume II numerical model (Rifai et al., 1988) can be used to evaluate critical groundwater fate and transport processes that may be involved in some of the migration pathways to human and ecological receptors. Quantitative fate and transport analyses can be used to determine what level and extent of remediation is required. Where remedial systems are in place or are in development (such as at FT-1), assumptions on the effectiveness of these systems at reducing source and mass, reducing dissolved contaminant concentrations in the groundwater, or increasing the availability of electron acceptors can also be included in the models.

An accurate estimate of the potential for natural biodegradation of BTEX and CAH compounds in groundwater is important to consider when determining whether fuel hydrocarbon or chlorinated solvent contamination presents a substantial threat to human health or the environment, and when designing a cost-effective remedial system capable of eliminating or abating these threats. Over the past two decades, numerous laboratory and field studies have demonstrated that subsurface microorganisms can degrade a variety of hydrocarbons (Lee, 1988). This process occurs naturally when sufficient oxygen (or other electron acceptors) and nutrients are available in the groundwater. The rate of natural biodegradation is generally limited by the lack of oxygen (or other electron acceptors) rather than by the lack of nutrients such as The supply of oxygen to unsaturated soil is constantly nitrogen or phosphorus. renewed by the vertical diffusion from the atmosphere. The natural biodegradation of CAHs occurs through the process of cometabolism in which enzymes or cofactors produced during the degradation of organic materials in the aquifer serve as catalysts in the degradation of CAHs. Norris et al. (1994) documents theory and research related to the cometabolism of CAH compounds.

2.2.2 Biodegradation of Dissolved BTEX Contamination

The positive effect of natural attenuation processes (e.g., advection, dispersion, sorption, and biodegradation) on reducing the actual mass of contamination dissolved in groundwater has been termed intrinsic remediation. Intrinsic remediation is advantageous for the following reasons:

- Contaminants are transformed to innocuous byproducts (e.g., carbon dioxide and water), not just transferred to another phase or location within the environment;
- Current pump-and-treat technologies are energy-intensive and generally not as effective in reducing residual contamination;
- The process is nonintrusive and allows continuing use of infrastructure during remediation;
- Current engineered remedial technologies may pose a greater risk to potential receptors than intrinsic remediation because contaminants may be transferred into the atmosphere during remediation activities; and
- Intrinsic remediation is far less costly than conventional, engineered remedial technologies.

To estimate the impact of natural attenuation on the fate and transport of BTEX compounds dissolved in groundwater at a site, two important lines of evidence must be demonstrated (Wiedemeier et al., 1995). The first is a documented loss of contaminants at the field scale. To supplement evidence provided by historical site data, dissolved concentrations of biologically recalcitrant tracers found in most fuel contamination are used in conjunction with aquifer hydrogeologic parameters, such as groundwater seepage velocity and dilution, to demonstrate that a reduction in contaminant mass is occurring at the site. The second line of evidence involves the use of chemical analytical data in mass balance calculations to show that areas with BTEX contamination can be correlated to areas with depleted electron acceptor (e.g., oxygen, nitrate, and sulfate) concentrations and increases in metabolic fuel degradation byproduct concentrations (e.g., methane and ferrous iron). With this site-specific information, groundwater flow and solute transport models can be used to simulate the fate and transport of dissolved BTEX compounds under the influence of natural attenuation.

To estimate the impact of cometabolism on the fate and transport of CAH compounds dissolved in groundwater at a site, two lines of evidence analogous to the BTEX evidence will be investigated. Once again, the first is documented loss of contaminants at the field scale and involves interpretations of historical data and the use of conservative tracers. The second line of evidence involves the use of chemical analytical data to demonstrate the transformation of the source solvent to daughter products and subsequent degradation to innocuous end products.

Analytical and numerical models are available for modeling the fate and transport of fuel hydrocarbons under the influence of advection, dispersion, sorption, and natural aerobic and anaerobic biodegradation. Analytical models may be used in conjunction with the Bioplume II numerical model, as appropriate or to simulate fate and transport of CAH compounds. The Bioplume II numerical model is based upon the USGS two-dimensional (2-D) solute transport model, which has been modified to include a biodegradation component that is activated by a superimposed plume of dissolved oxygen. Bioplume II solves the USGS 2-D solute equation twice, once for hydrocarbon concentrations in the groundwater and once for a dissolved oxygen plume. The two plumes are then combined using superimposition at every particle move to simulate biological reactions between fuel products and oxygen. As appropriate, biodegradation of contaminants by anaerobic processes is simulated using a first-order anaerobic decay rate.

The analytical solute transport models are derived from advection-dispersion equations given by Wexler (1992) and van Genuchten and Alves (1982). These models provide exact, closed-form solutions and are appropriately used for relatively simple hydrogeologic systems that are homogeneous and isotropic. Each model is capable of simulating advection, dispersion, sorption, and biodegradation (or any first-order decay process). These models can simulate continuous or decaying sources. A continuous-source model is useful for determination of the worst-case distribution of the dissolved contaminant plume. A decaying-source model is useful for simulating source removal scenarios, including natural weathering processes and engineered solutions.

2.2.3 Initial Conceptual Site Model

Site FT-1 geologic data were previously integrated to produce two geologic cross-sections of the site. Cross sections A - A' and B - B' (Figures 2.6 and 2.7) show the dominant hydrostratigraphic units present at the site and the elevation of the water table. Figure 2.8 is a groundwater surface map prepared using October 1992 groundwater elevation data (HNUS, 1993a).

The surface of the groundwater table is present at approximately 4 to 6 feet bgs in unconsolidated deposits which are primarily sand and gravel glacial deposits in the vicinity of the site. Groundwater also occurs in shallow bedrock, which is present at 9 to 30 feet bgs. Groundwater flow in the unconsolidated material is east-southeast, with an average gradient of 0.002 ft/ft that steepens near the source area and just beyond the Base boundary to approximately 0.007 ft/ft. On the basis of the available data, Parsons ES will model the site as an unconfined, fine- to coarse-grained sand and gravel aquifer. This CSM will be modified as necessary as additional site hydrogeologic data become available.

Mobile LNAPL has not been identified at FT-1. However, if it is encountered, it may be necessary to use the fuel/water partitioning models of Bruce et al. (1991) or Cline et al. (1991) to provide a conservative source term to model the partitioning of BTEX compounds from the free-product phase into the groundwater. In order to use one of these models, samples of product will be collected and analyzed for mass fraction of BTEX compounds. If LNAPL is present, Parsons ES will attempt to collect groundwater samples from immediately below the LNAPL layer, if possible.

The site-specific remedial goal for FT-1, as specified in the ROD is to remediate groundwater until benzene concentrations below 5 μ g/L are attained across the site (HNUS, 1993b). However, the synergistic effects of all of the BTEX compounds on attenuation rates make site data on all of the BTEX compounds important. Additionally, TCE and the associated breakdown products have been indicated to be chemicals of potential concern at the site (HNUS, 1993b). All of the BTEX compounds, TCE, and the daughter products of TCE (CDCE, tDCE, and VC) will be the focus of this intrinsic remediation study because of their regulatory importance. Analytical groundwater flow and solute transport models will be used to simulate the migration and degradation of the chemicals of concern at FT-1 and will be used to predict the concentration and extent of the groundwater contaminant plume over time.

The BTEX compounds at the site are expected to leach from contaminated soil, which is known to contain fuel residuals (Table 2.3), into the groundwater and migrate with the dissolved CAH compounds downgradient as a dissolved contaminant plume. It is suspected that CAH compounds may be present in the groundwater as the result of an upgradient source because they have been detected in groundwater samples from upgradient wells and have not been detected in site soil samples. In addition to the effects of mass transport mechanisms (volatilization, dispersion, diffusion, and adsorption), these dissolved contaminants will likely be removed from the groundwater system by naturally occurring destructive attenuation mechanisms, such as biodegradation or biologically induced cometabolism. The effects of these transport and fate processes on the dissolved groundwater plume will be investigated using the quantitative groundwater analytical data and groundwater flow and solute transport models. Data collection and analysis requirements are discussed in Section 3 of this work plan.

2.2.4 Potential Groundwater Pathways and Receptors

Potential preferential contaminant migration pathways such as groundwater discharge points and subsurface utility corridors (artificial conduits) will be identified during the field work phase of this project. The primary potential migration path for BTEX contamination at FT-1 results from the leaching of residual fuels from contaminated site soils into the groundwater. Dissolved concentrations of BTEX and CAHs can be transported with migrating groundwater to potential receptors, who could be exposed via ingestion or incidental contact. There are residential water wells located within one-half mile downgradient from the site. Base drinking water does not come from wells located near or downgradient from FT-1.

SECTION 3

COLLECTION OF ADDITIONAL DATA

To complete the TS and to demonstrate that intrinsic remediation of fuel-related contaminants and chlorinated solvents is occurring, additional site-specific hydrogeologic data will be collected. The physical and chemical hydrogeologic parameters listed below will be determined during the field work phase of the TS.

Physical hydrogeologic characteristics to be determined include:

- Depth from measurement datum to the groundwater surface in site monitoring wells;
- Locations of potential groundwater preferential flow pathways and recharge and discharge areas;
- · Locations of downgradient wells and their uses;
- · Hydraulic conductivity through slug tests, as required;
- Estimate of dispersivity, where possible;
- Stratigraphic analysis of subsurface media;
- Groundwater temperature; and
- Determination of extent and thickness of mobile and residual LNAPL (if present).

Chemical hydrogeologic characteristics to be determined include:

- Dissolved oxygen concentrations;
- Specific conductance;
- pH;
- Chemical analysis of any mobile LNAPL (if present) to determine mass fraction of BTEX; and
- Additional chemical analysis of groundwater and soil for the parameters listed in Table 3.1.

In order to obtain these data, soil, groundwater, and, if present, free product samples will be collected and analyzed. The following sections describe the procedures that will be followed when collecting additional site-specific data. Soil sampling and monitoring point installation will be accomplished using the Geoprobe® system as described in Sections 3.1 and 3.2. Soil core sample collection procedures are described in Section 3.1. Monitoring point installation procedures are described in Section 3.2. Groundwater sampling procedures for monitoring wells and newly installed groundwater monitoring points are described in Section 3.3. Measurement procedures for aquifer parameters (e.g., hydraulic conductivity) are described in Section 3.4.

3.1 SOIL SAMPLING

The following sections describe sampling locations, sample collection techniques, equipment decontamination procedures, site restoration, and management of investigation-derived waste materials.

3.1.1 Soil Sample Locations and Required Analyses

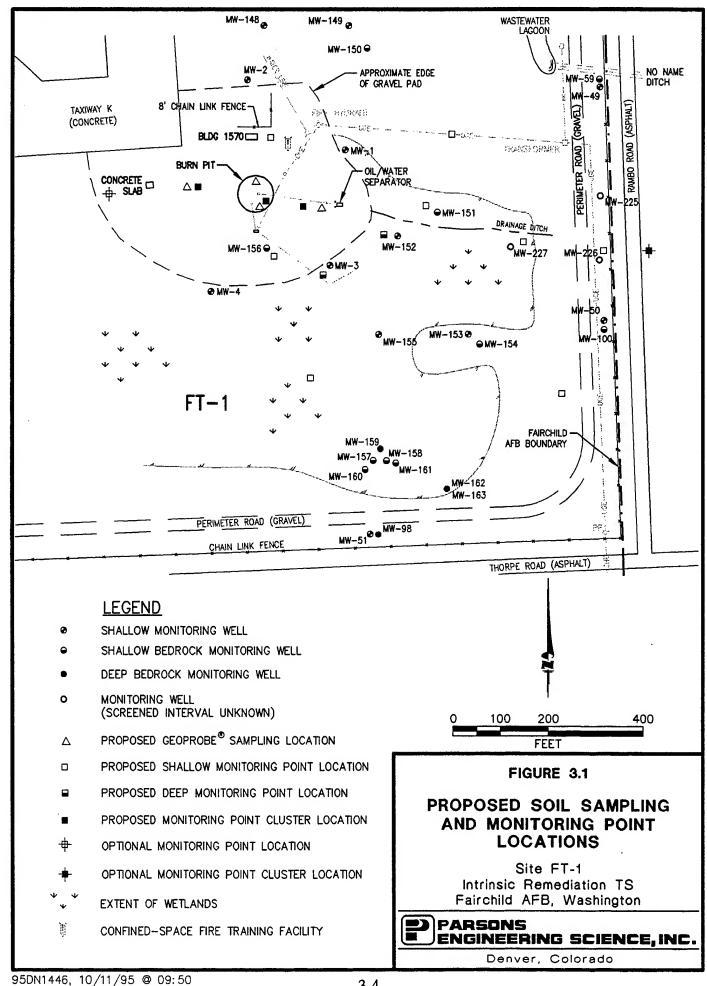

Soil samples will be collected at all Geoprobe® and monitoring point installation locations. Figure 3.1 identifies four proposed locations for soil sample collection at FT-1. Table 3.1 presents an analytical protocol for soil samples, and Appendix A contains detailed information on the analyses and methods to be used during this sampling effort.

A minimum of two samples will be collected from each Geoprobe[®] hole location. One sample will be taken at the water table, and one will be taken at the depth of maximum BTEX contamination as determined by soil headspace screening. Sampling locations include the suspected source areas on the northern and southern edges of the burn pit, upgradient from the burn pit mid way between the burn pit and the concrete slab, and 150 feet downgradient from the burn pit just west of the oil/water separator. Additional samples will be collected at the discretion of the Parsons ES field scientist.

A portion of each sample will be used to measure soil headspace, and another portion of selected samples will be delivered to the USEPA mobile laboratory for analytical analysis. Each laboratory soil sample will be placed in an analyte-appropriate sample container and hand-delivered to USEPA field personnel for analysis of total hydrocarbons, aromatic hydrocarbons, and moisture content using the procedures presented in Table 3.1. In addition, at least two samples will be analyzed for TOC from locations upgradient, crossgradient, or far downgradient from the contaminant source. Each headspace screening sample will be placed in a sealed plastic bag or mason jar and allowed to sit for at least 5 minutes. VOCs in soil headspace will then be determined using an organic vapor meter (OVM), and the results will be recorded in the field records by the Parsons ES field scientist.

3.1.2 Sample Collection Using the Geoprobe® System

Soil samples will be collected using a Geoprobe® system, a hydraulically powered percussion/probing machine capable of advancing sampling tools through

unconsolidated soils. This system allows the rapid collection of soil, soil gas, and groundwater samples at shallow depths while minimizing the generation of investigation-derived waste materials. Figure 3.2 is a diagram of the Geoprobe® system.

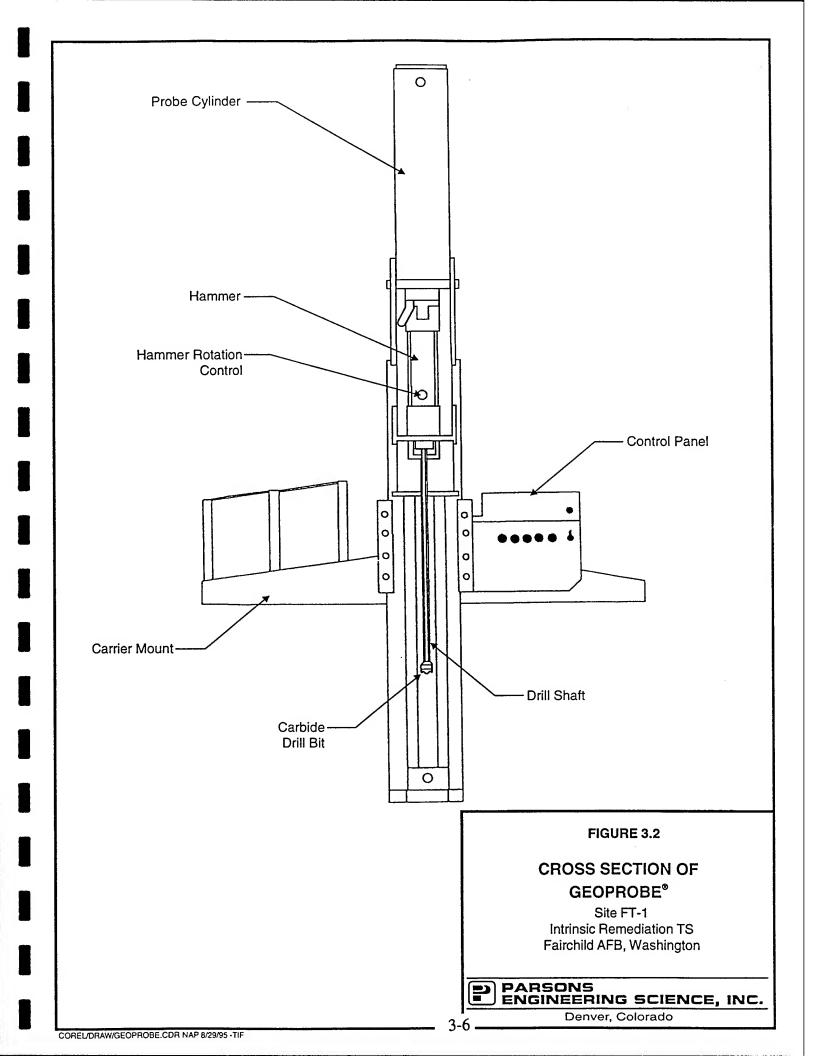

Soil samples will be collected using a probe-drive sampler. The probe-drive sampler serves as both the driving point and the sample collection device and is attached to the leading end of the probe rods. To collect a soil sample, the sampler is pushed or driven to the desired sampling depth, the drive point is retracted to open the sampling barrel, and the sampler is subsequently pushed into the undisturbed soils. The soil cores are retained within brass, stainless steel, or clear acetate liners inside the sampling barrel. The probe rods are then retracted, bringing the sampling device to the surface. The soil sample can then be extruded from the liners for lithologic logging, or the liners can be capped, and undisturbed samples can be submitted to the analytical laboratory for testing.

If the probe-drive sampling techniques described above are inappropriate, inadequate, or unable to efficiently provide sufficient soil samples for the characterization of the site, continuous soil samples will be obtained from conventional soil boreholes using a hand auger or similar method judged acceptable by the Parsons ES field scientist. Procedures will be modified, if necessary, to ensure good sample recovery.

The Parsons ES field scientist will be responsible for observing all field investigation activities, maintaining a detailed descriptive log of all subsurface materials recovered during soil coring, photographing representative samples, and properly labeling and storing samples. An example of the proposed geologic log form is presented in Figure 3.3. The descriptive log will contain:

- Sample interval (top and bottom depth);
- Sample recovery;
- Presence or absence of contamination;
- Lithologic description, including relative density, color, major textural constituents, minor constituents, porosity, relative moisture content, plasticity of fines, cohesiveness, grain size, structure or stratification, relative permeability, and any other significant observations; and
- Depths of lithologic contacts and/or significant textural changes measured and recorded to the nearest 0.1 foot.

Base personnel will be responsible for identifying the location of all utility lines, USTs, fuel lines, or any other underground infrastructure prior to any sampling activities. All necessary digging permits will be obtained by Base personnel prior to mobilizing to the field. Base personnel will also be responsible for acquiring drilling and monitoring point installation permits for the proposed locations. Parsons ES will be responsible for providing trained operators for the Geoprobe[®].

3.1.3 Datum Survey

The horizontal location of all soil sampling locations relative to established Base coordinates will be measured by a surveyor. Horizontal coordinates will be measured to the nearest 0.1 foot. The elevation of the ground surface also will be measured to the nearest 0.1 foot relative to USGS msl data.

3.1.4 Site Restoration

After sampling is complete, each sampling location that is not converted to use as a groundwater monitoring point will be restored as closely to its original condition as possible. Holes created by the Geoprobe® in sandy soils similar to those found at the Base tend to cave in soon after extraction of the drive sampler. However, any test holes remaining open after extraction of the probe-drive will be sealed with hydrated bentonite chips, pellets, or grout to eliminate any creation or enhancement of contaminant migration pathways to the groundwater. Soil sampling using the Geoprobe® creates low volumes of soil waste. Soil not used for sampling will be placed in 55-gallon drums, labeled, and transported to a Base-designated holding location while disposal is being arranged.

3.1.5 Equipment Decontamination Procedures

Prior to arriving at the site, and between each sampling location, probe rods, tips, sleeves, pushrods, samplers, tools, and other downhole equipment will be decontaminated using a high-pressure, steam/hot water wash or Alconox® wash with a potable water rinse. Between each soil sample, the sampling barrel will be disassembled and decontaminated with Alconox® and potable water. The barrel then will be rinsed with deionized water and reassembled with new liners. Between uses, the sampling barrel will be wrapped in clean plastic or foil to prevent contamination. Only potable water will be used for decontamination.

All rinseate will be collected in 55-gallon drums. Filled 55-gallon drums will be labeled and transported to a Base-designated holding location while disposal is being arranged. The Base will be responsible for signing required waste shipping and disposal manifests.

Potable water to be used during equipment cleaning, decontamination, or grouting will be obtained from one of the Base water supplies. Water use approval will be verified by contacting the appropriate facility personnel. The field scientist will make the final determination as to the suitability of site water for these activities. Precautions will be taken to minimize any impact to the surrounding area that might result from decontamination operations.

3.2 MONITORING POINT INSTALLATION

To further characterize site hydrogeologic conditions, approximately 16 groundwater monitoring points will be installed at FT-1 to supplement the site monitoring wells. The following sections describe the proposed monitoring point locations and completion intervals, monitoring point installation, monitoring point development, and equipment decontamination procedures.

3.2.1 Monitoring Point Locations and Completion Intervals

The locations of 16 proposed groundwater monitoring points at FT-1 are identified on Figure 3.1. The proposed locations for the new monitoring points were determined from a review of data gathered during previous site activities. Monitoring point locations were selected to provide hydrogeologic data necessary for successful implementation of the Bioplume II model and to monitor potential fuel hydrocarbon migration from the site. Monitoring point locations were selected to define four aspects of the site: 1) the magnitude of the dissolved BTEX concentrations within suspected source areas, 2) the extent of contamination, 3) the horizontal distribution of dissolved BTEX, and 4) the hydrogeology and groundwater flow direction at the site. The proposed locations shown on Figure 3.1 may be modified in the field as a result of encountered field conditions and acquired field data.

Eight monitoring points will be installed within the extent of the gravel pad surrounding the suspected source area. One monitoring point cluster will be installed in the southeastern corner of the burn pit. Another monitoring point cluster will be installed approximately 100 feet downgradient of the burn pit. A third monitoring point cluster will be installed roughly 100 feet upgradient of the burn pit to verify the upgradient limit of contamination. Shallow monitoring points also will be installed approximately 100 feet north and 100 feet south of the burn pit to investigate the lateral extent of contamination to the north and south. The sampling locations are necessary because groundwater in the unconsolidated deposits underlying the gravel pad has not been characterized in previous investigations and is suspected to have elevated concentrations of dissolved BTEX and possibly solvents.

Two deep monitoring points will be installed in the unconsolidated deposits just beyond the downgradient edge of the gravel pad. These deep points will be placed near shallow monitoring wells MW-3 and MW-152 and will aid in determining the vertical extent of contamination in the unconsolidated material immediately downgradient from the suspected source area. Additionally, six shallow monitoring points will be installed downgradient from the gravel pad and at the top of the saturated zone to fully delineate the downgradient extent of contamination and to more accurately characterize the plume downgradient from the gravel pad. Shallow monitoring points will be installed near MW-151, MW-227, MW-226, 150 feet southwest of MW-155, 150 feet north of MW-151, and 250 feet southeast of MW-154. These shallow points will be used to complement existing monitoring well locations for the purpose of full plume delineation. Additional monitoring points and/or the exact placement of monitoring points may be modified by the field scientist as additional site information becomes available.

Each shallow monitoring point will have a screened interval of approximately 3 feet placed near the top of the saturated zone in the unconsolidated deposits. Deep monitoring points will be placed in these deposits immediately above the bedrock basalt. The exact depth and location of monitoring points will be determined by the Parsons ES field scientist on the basis of site conditions. The proposed screened intervals of approximately 3 feet or less will help mitigate the dilution of water samples from potential vertical mixing of contaminated and uncontaminated groundwater in the monitoring point casing. Adjustments of the depth and length of the screened interval

of the monitoring points may be necessary in response to actual aquifer conditions and contaminant distribution identified during Geoprobe® testing.

3.2.2 Monitoring Point Installation Procedures

3.2.2.1 Pre-Placement Activities

All necessary digging, coring, and drilling permits will be obtained prior to mobilizing to the field. In addition, all utility lines will be located, and proposed Geoprobe[®] locations will be cleared prior to any intrusive activities. Responsibilities for these permits and clearances are discussed in Section 3.1.1.

Water to be used in monitoring point installation and equipment cleaning will be obtained from one of the Base water supplies. Water use approval will be verified by contacting the appropriate facility personnel. The field scientist will make the final determination as to the suitability of site water for these activities.

3.2.2.2 Monitoring Point Materials Decontamination

Monitoring point installation and completion materials will be inspected by the field scientist and determined to be clean and acceptable prior to use. If not factory sealed, the well points and tubing will be cleaned prior to use with a high-pressure, steam/hot-water cleaner using approved water. Materials that cannot be cleaned to the satisfaction of the field scientist will not be used.

3.2.2.3 Installation and Materials

This section describes the procedures to be used for installation of monitoring points. Monitoring points will be installed using either 0.375-inch Teflon® tubing connected to a 0.5-inch-diameter stainless steel screen or a 0.5-inch inside-diameter (ID)/0.75-inch outside-diameter (OD) polyvinyl chloride (PVC) screen and casing.

If subsurface conditions permit, shallow monitoring points will be constructed of 0.75-inch OD-/0.5-inch-ID PVC casing and well screen to provide additional water level information. Approximately 3 feet of factory-slotted screen will be installed for each shallow monitoring point. Effective installation of the shallow monitoring points requires that the boreholes remain open upon completion of drilling. Shallow 0.5-inch-ID PVC monitoring points will be installed by punching and sampling a borehole with the Geoprobe[®]. Upon removing the rods, the borehole depth will be measured to determine if the hole remains open. If the borehole remains open, the 0.5-inch-ID PVC casing and screen will be placed at the appropriate depths. The annular space around the screen will be filled with sand filter pack, and the annulus around the casing will be filled with grout or bentonite. Monitoring point construction details will be noted on a Monitoring Point Installation Record form (Figure 3.4). This information will become part of the permanent field record for the site.

Monitoring point screens will be constructed of flush-threaded, Schedule 40 PVC with an ID of 0.5 inch. The screens will be factory slotted with 0.01-inch openings. Shallow monitoring point screens will be placed to sample and provide water level information at or near the water table. Blank monitoring point casing will be

constructed of Schedule 40 PVC with an ID of 0.5 inch. All monitoring point casing sections will be flush-threaded; joints will not be glued. The casing at each monitoring point will be fitted with a bottom cap and a top cap constructed of PVC.

If subsurface conditions do not permit the boreholes to remain open (i.e. the formation collapses in the hole), monitoring points will be constructed of a sacrificial drive point attached to a length of 0.5-inch-diameter stainless steel mesh that functions as the well screen, which in turn is connected to 0.375-inch Teflon® tubing. Holes are less likely to remain open for the installation of the deeper top-of-bedrock wells than the shallower top-of-water-table wells. To install tubing-cased monitoring points, the borehole is punched and sampled to several feet above the target depth for the monitoring point. The probe rods are withdrawn from the borehole, and the soil sampler is replaced with the well point assembly. An appropriate length of Teflon® tubing is threaded through the probe rods and attached to the well point. The assembly is lowered into the borehole and then driven down to the target depth and sampling zone. The probe rods are removed, leaving the sacrificial tip, screen assembly, and tubing behind. The soil is likely to cave in around the screen and tube assembly; where this does not occur, silica sand will be emplaced to create a sand pack around the well point, and the borehole annular space around the tubing above the sand pack will be filled with granular bentonite or grout to seal it. Monitoring point construction details will be noted on a Monitoring Point Installation Record form (Figure 3.4).

Should 0.5-inch-ID PVC shallow monitoring points not be installed, the only resulting data gap would be the lack of water level information for that particular location. The decision to install 0.5-inch-ID PVC monitoring points will be made in the field once the open-hole stability of subsurface soils and Geoprobe® equipment can be evaluated.

The field scientist will verify and record the total depth of the monitoring point, the lengths of all casing sections, and the depth to the top of all monitoring point completion materials. All lengths and depths will be measured to the nearest 0.1 foot.

3.2.2.4 Monitoring Point Completion

Monitoring points will be completed at grade with a protective cover cemented in place. The protective cover will be raised slightly above the ground surface, with a 2-foot-square concrete pad that will slope gently away from the cover to facilitate runoff during precipitation events. After monitoring point completion, each site will be restored as closely as possible to its original condition.

3.2.3 Monitoring Point Development and Records

The new monitoring points will be developed prior to sampling to remove fine sediments from the portion of a formation adjacent to the screen. Development will be accomplished by lowering high-density polyethylene (HDPE) tubing into the well or attaching Teflon® tubing to the pump lines and removing water with a peristaltic pump until pH, temperature, specific conductivity, and water clarity (turbidity) stabilize. At a minimum, 10 casing volumes of water will be developed from each monitoring point. In the event that 10 casing volumes of water cannot be recovered as a result of low water production, the water volume recovered and the deficiency will be noted in the

development records. Monitoring point development will occur a minimum of 24 hours prior to sampling.

A development record will be maintained for each new monitoring point. The development record will be completed in the field by the field scientist. Figure 3.5 is an example of a development record used for similar well installations. Development records will include:

- Monitoring point number;
- Date and time of development;
- Development method;
- Monitoring point depth;
- Volume of water produced;
- · Description of water produced;
- Post-development water level and monitoring point depth (0.5-inch ID PVC monitoring points only); and

Field analytical measurements, including pH and specific conductivity.

Development waters will be collected in 55-gallon drums. Filled 55-gallon drums will be labeled and transported to a Base-designated holding location while disposal is being arranged. The Base will be responsible for signing required shipping and disposal manifests.

3.2.4 Monitoring Point Location and Datum Survey

The location and elevation of the monitoring points will be surveyed by a registered surveyor soon after completion. Horizontal coordinates will be measured to the nearest 0.1 foot relative to established Base coordinates. The elevation of the flush-mount casing and measurement datum (top of interior casing) will be measured to the nearest 0.01 foot relative to USGS msl data.

3.2.5 Water Level Measurements

Water levels at all site monitoring points and wells will be measured within a short time period so that the water level data are comparable. The depth to water below the measurement datum will be measured to the nearest 0.01 foot using an electric water level probe or, if mobile LNAPL is present, an oil-water interface probe.

3.3 GROUNDWATER SAMPLING PROCEDURES

This section describes the scope of work required for collection of groundwater quality samples. Samples will be collected from previously installed monitoring wells and newly installed monitoring points. A peristaltic pump with dedicated HDPE tubing will be used to collect groundwater samples at monitoring points and wells. Samples

Intrinsic Remediation TS Fairchild AFB, Washington

PARSONS ENGINEERING SCIENCE, INC. are planned to be collected at monitoring wells MW-1, MW-2, MW-3, MW-4, MW-49, MW-50, MW-52, MW-53, MW-59, MW-61, MW-100, MW-151, MW-152, MW-153, MW-154, MW-155, MW-156, MW-225, MW-226, MW-227, and all 16 new monitoring points (Figures 1.3 and 3.1). In order to maintain a high degree of QC during this sampling event, the procedures described in the following sections will be followed.

Sampling will be conducted by qualified scientists and technicians from Parson ES and the USEPA NRMRL who are trained in the conduct of groundwater sampling, records documentation, and chain-of-custody procedures. In addition, sampling personnel will have thoroughly reviewed this work plan prior to sample acquisition and will have a copy of the work plan available onsite for reference. Groundwater sampling includes the following activities:

- · Assembly and preparation of equipment and supplies;
- Inspection of the monitoring well/point integrity including:
 - Protective cover, cap, and lock,
 - External surface seal and pad,
 - Monitoring well/point stick-up, cap, and datum reference, and
 - Internal surface seal;
- Groundwater sampling, including:
 - Water level and product thickness measurements,
 - Visual inspection of sample water,
 - Monitoring well/point casing evacuation, and
 - Sample collection;
- Sample preservation and shipment, including:
 - Sample preparation,
 - Onsite measurement of physical parameters, and
 - Sample labeling;
- · Completion of sampling records; and
- Sample disposition.

Detailed groundwater sampling and sample handling procedures are presented in following sections.

3.3.1 Preparation for Sampling

All equipment to be used for sampling will be assembled and properly cleaned and calibrated (if required) prior to arriving in the field. In addition, all record-keeping materials will be gathered prior to leaving the office.

3.3.1.1 Equipment Cleaning

All portions of sampling and test equipment that will contact the sample matrix will be thoroughly cleaned before each use. This includes the split-spoon soil samplers, sampling pumps, water level probe and cable, test equipment for onsite use, and other equipment or portions thereof that will contact the samples. Given the types of sample analyses to be conducted, the following cleaning protocol will be used:

Wash with potable water and phosphate-free laboratory detergent (HP-II detergent solutions, as appropriate);

- Rinse with potable water;
- Rinse with isopropyl alcohol;
- · Rinse with distilled or deionized water; and
- Air dry.

Any deviations from these procedures will be documented in the field scientist's field notebook and on the groundwater sampling record (Figure 3.6).

If precleaned disposable sampling equipment is used, the cleaning protocol specified above will not be required. Laboratory-supplied sample containers will be cleaned and sealed by the laboratory. The type of container provided and the method of container decontamination will be documented in the USEPA mobile laboratory's permanent record of the sampling event.

3.3.1.2 Equipment Calibration

As required, field analytical equipment will be calibrated according to the manufacturers' specifications prior to field use. This applies to equipment used for onsite measurements of dissolved oxygen (DO), pH, electrical conductivity, temperature, reduction/oxidation (redox) potential, sulfate, nitrate, ferrous iron (Fe²⁺), and other field parameters listed on Table 3.1.

3.3.2 Sampling Procedures

Special care will be taken to prevent contamination of the groundwater and extracted samples. The primary ways in which sample contamination can occur is through contact with improperly cleaned sampling equipment. To prevent such contamination, the water level probe and cable used to determine static water levels and total well/point depths will be thoroughly cleaned before and after field use and between uses at different sampling locations according to the procedures presented in Section 3.3.1.1. Dedicated tubing will be used at each well/point developed, purged, and/or sampled with the peristaltic pump. In addition to the use of properly cleaned equipment, a clean pair of new, disposable nitrile or latex gloves will be worn each time a different monitoring point or well is sampled. The following paragraphs present the procedures to be followed for groundwater sample collection from groundwater monitoring points and wells. These activities will be performed in the order presented

GROUNDWATER SAMPLING RECORD

Site FT-1 Intrinsic Remediation TS Fairchild AFB, Washington

PARSONS ENGINEERING SCIENCE, INC.

Denver, Colorado

below. Exceptions to this procedure will be noted in the field scientist's field notebook or on the groundwater sampling record.

3.3.2.1 Preparation of Location

Prior to starting the sampling procedure, the area around the monitoring points/wells will be cleared of foreign materials, such as brush, rocks, and debris. These procedures will prevent sampling equipment from inadvertently contacting debris around the monitoring point/well.

3.3.2.2 Water Level and Total Depth Measurements

Prior to removing water from the monitoring point/well, the static water level will be measured. An electric water level probe or oil/water interface probe will be used to measure the depth to groundwater below the datum to the nearest 0.01 foot. After measuring the static water level, the water level probe will be slowly lowered to the bottom of the monitoring point/well and the depth will be measured to the nearest 0.01 foot. If free-phase product (mobile LNAPL) is present, the total depth of the well from installation records will be used to avoid excessive contamination of the water level probe and cord. Based on these measurements, the volume of water to be purged from the monitoring point/well will be calculated. If mobile LNAPL is encountered, the thickness of the product will be measured with an oil/water interface probe.

3.3.2.3 Monitoring Point/Well Purging

The volume of water contained within the monitoring point/well casing at the time of sampling will be calculated, and at least three times the calculated volume will be removed from the well. A peristaltic pump will be used for monitoring point/well purging. All purge waters will be collected in 55-gallon drums. Filled 55-gallon drums will be labeled and transported to a Base-designated holding location while disposal is being arranged. The Base will be responsible for signing required shipping and disposal manifests.

If a monitoring point or well is evacuated to a dry state during purging, the point/well will be allowed to recharge, and the sample will be collected as soon as sufficient water is present in the monitoring point/well to obtain the necessary sample quantity. Sample compositing or sampling over a lengthy period by accumulating small volumes of water at different times to obtain a sample of sufficient volume will not be allowed.

3.3.2.4 Sample Extraction

Dedicated HDPE tubing and a peristaltic pump will be used to extract groundwater samples from monitoring points and wells. The tubing will be lowered through the casing into the water gently to prevent splashing. This step is omitted if the monitoring point is constructed of Teflon® tubing. The sample will be transferred directly into the appropriate sample container. The water will be carefully poured down the inner walls of the sample bottle to minimize aeration of the sample.

Unless other instructions are given by the USEPA mobile laboratory, sample containers will be completely filled so that no air space remains in the container. Excess water collected during sampling will be disposed of in the same manner as purge water.

3.3.3 Onsite Groundwater Parameter Measurement

As indicated on Table 3.1, many of the groundwater chemical parameters will be measured onsite by USEPA staff. Some of the measurements will be made with direct-reading meters, while others will be made using a HACH® portable colorimeter in accordance with specific HACH® analytical procedures. These procedures are described in the following subsections.

All glassware or plasticware used in the analyses will have been cleaned prior to sample collection by thoroughly washing with a solution of laboratory-grade, phosphate-free detergent (e.g., Alconox®) and water, and rinsing with isopropyl alcohol and deionized water to prevent interference or cross-contamination between measurements. If concentrations of an analyte are above the range detectable by the titrimetric or colorimetric methods, the analysis will be repeated by diluting the groundwater sample with distilled water until the analyte concentration falls to a level within the range of the method. All rinseate and sample reagents accumulated during groundwater analysis will be collected in glass containers fitted with screw caps and properly disposed.

3.3.3.1 Dissolved Oxygen Measurements

DO measurements will be made using a meter with a downhole oxygen sensor or a sensor in a flow-through cell before and immediately following groundwater sample acquisition. When DO measurements are taken in monitoring points/wells that have not yet been sampled, the monitoring points/wells will be purged until DO levels stabilize.

3.3.3.2 pH, Temperature, and Specific Conductance

Because the pH, temperature, and specific conductance of a groundwater sample can change significantly within a short time following sample acquisition, these parameters will be measured in the field in unfiltered, unpreserved, "fresh" water collected by the same technique as the samples taken for laboratory analyses. The measurements will be made in a flow-through cell or a clean glass container separate from those intended for laboratory analysis, and the measured values will be recorded in the groundwater sampling record (Figure 3.6).

3.3.3.3 Alkalinity Measurements

Alkalinity in groundwater helps buffer the groundwater system against acids generated through both aerobic and anaerobic biodegradation processes. Alkalinity of the groundwater sample will be measured in the field by experienced USEPA NRMRL scientists via titrimetric analysis using USEPA-approved HACH® Method 8221 (0 to 5,000 mg/L as calcium carbonate) or a similar method. Alkalinity of the groundwater

sample also will be measured at the fixed-based laboratory using USEPA method 310.1.

3.3.3.4 Nitrate- and Nitrite-Nitrogen Measurements

Nitrate-nitrogen concentrations are of interest because nitrate can act as an electron acceptor during hydrocarbon biodegradation under anaerobic soil or groundwater conditions. Nitrate-nitrogen is also a potential nitrogen source for biomass formation for hydrocarbon-degrading bacteria. Nitrite-nitrogen is an intermediate byproduct in both ammonia nitrification and in nitrate reduction in anaerobic environments.

Nitrate- and nitrite-nitrogen concentrations in groundwater will be measured in the field by experienced USEPA NRMRL scientists via colorimetric analysis using a HACH® DR/700 Portable Colorimeter. Nitrate concentrations in groundwater samples will be analyzed after preparation with HACH® Method 8039 (0 to 30.0 mg/L NO₃). Nitrite concentrations in groundwater samples will be analyzed after preparation with EPA-approved HACH® Method 8507 (0 to 0.35 mg/L NO₂) or a similar method.

3.3.3.5 Carbon Dioxide Measurements

Carbon dioxide concentrations in groundwater will be measured in the field by USEPA NRMRL scientists via titrimetric analysis using HACH® Method 1436-01 (0 to 250 mg/L as CO₂). Sample preparation and disposal procedures are the same as outlined at the beginning of Section 3.3.3.

3.3.3.6 Sulfate Measurements

Sulfate in groundwater is a potential electron acceptor for fuel-hydrocarbon biodegradation in anaerobic environments. A USEPA NRMRL scientist will measure sulfate concentrations via colorimetric analysis with a HACH® DR/700 Portable Colorimeter. After appropriate sample preparation. EPA-approved HACH® Method 8051 (0 to 70.0 mg/L SO₄) or similar will be used to prepare samples and analyze sulfate concentrations.

3.3.3.7 Total Iron, Ferrous Iron, and Ferric Iron Measurements

Iron is an important trace nutrient for bacterial growth, and different states of iron can affect the redox potential of the groundwater and act as an electron acceptor for biological metabolism under anaerobic conditions. Iron concentrations will be measured in the field via colorimetric analysis with a HACH® DR/700 Portable Colorimeter after appropriate sample preparation. HACH® Method 8008 (or similar) for total soluble iron (0 to 3.0 mg/L Fe³⁺ + Fe²⁺) and HACH® Method 8146 (or similar) for ferrous iron (0 to 3.0 mg/L Fe²⁺) will be used to prepare and quantitate the samples. Ferric iron will be quantitated by subtracting ferrous iron levels from total iron levels.

3.3.3.8 Manganese Measurements

Manganese is a potential electron acceptor under anaerobic environments. Manganese concentrations will be quantitated in the field using colorimetric analysis

with a HACH® DR/700 Portable Colorimeter. USEPA-approved HACH® Method 8034 (0 to 20.0 mg/L) or similar will be used for quantitation of manganese concentrations. Sample preparation and disposal procedures are outlined earlier in Section 3.3.3.

3.3.3.9 Reduction/Oxidation Potential

The redox potential of groundwater is an indication of the relative tendency of a solution to accept or transfer electrons. Redox reactions in groundwater are usually biologically mediated; therefore, the redox potential of a groundwater system depends upon and influences rates of biodegradation. Redox potential can be used to provide real-time data on the location of the contaminant plume, especially in areas undergoing anaerobic biodegradation. The redox potential of a groundwater sample taken inside the contaminant plume should be somewhat less than that taken in an upgradient location.

The redox potential of a groundwater sample can change significantly within a short time following sample acquisition and exposure to atmospheric oxygen. As a result, this parameter will be measured in the field in unfiltered, unpreserved, "fresh" water collected by the same technique as the samples taken for laboratory analyses. The measurements will be made as quickly as possible in a clean glass container separate from those intended for laboratory analysis or in a flow through cell.

3.4 SAMPLE HANDLING FOR LABORATORY ANALYSIS

This section describes the handling of samples from the time of sampling until the samples are delivered to USEPA field laboratory.

3.4.1 Sample Preservation

The USEPA mobile laboratory support personnel will add any necessary chemical preservatives prior to filling the sample containers. Samples will be prepared for transportation to the analytical laboratory by placing the samples in a cooler containing ice to maintain a shipping temperature of as close to 4 degrees centigrade (°C) as possible. Samples will be delivered promptly to USEPA field laboratory personnel, who will be responsible for shipment of appropriate samples to the NRMRL in Ada, Oklahoma for analysis.

3.4.2 Sample Containers and Labels

Sample containers and appropriate container lids will be provided by the USEPA field laboratory (see Appendix A). The sample containers will be filled as described in Section 3.3.2.4, and the container lids will be tightly closed. The sample label will be firmly attached to the container side, and the following information will be legibly and indelibly written on the label:

- · Facility name;
- Sample identification;
- Sample type (e.g., groundwater, soil);

- Sampling date;
- · Sampling time;
- Preservatives added;
- Sample collector's initials; and
- Requested analyses.

3.4.3 Sample Shipment

After the samples are sealed and labeled, they will be packaged for transport to the onsite USEPA field laboratory. The following packaging and labeling procedures will be followed:

- Package sample so that it will not leak, spill, or vaporize from its container;
- · Cushion samples to avoid breakage; and
- Add ice to container to keep samples cool.

The packaged samples will be delivered by hand to the USEPA field laboratory. Delivery will occur as soon as possible after sample acquisition.

3.4.4 Chain-of-Custody Control

Chain-of-custody documentation for the shipment of samples from the USEPA field laboratory to the NRMRL analytical laboratory in Ada, Oklahoma, will be the responsibility of the USEPA field personnel.

3.4.5 Sampling Records

In order to provide complete documentation of the sampling event, detailed records will be maintained by the field scientist. At a minimum, these records will include the following information:

- Sample location (facility name);
- Sample identification;
- Sample location map or detailed sketch;
- Date and time of sampling;
- Sampling method;
- Field observations of
 - Sample appearance, and

- Sample odor;
- Weather conditions;
- Water level prior to purging (groundwater samples only);
- Total monitoring well/point depth (groundwater samples only);
- Sample depth (soil samples only);
- Purge volume (groundwater samples only);
- Water level after purging (groundwater samples only);
- Monitoring well/point condition (groundwater samples only);
- Sampler's identification;
- Field measurements of pH, temperature, DO, and specific conductivity (groundwater samples only); and
- Any other relevant information.

Groundwater sampling information will be recorded on a groundwater sampling form. Figure 3.6 shows an example of the groundwater sampling record. Soil sampling information will be recorded in the field log book.

3.4.6 Laboratory Analyses

Laboratory analyses will be performed on all groundwater and soil samples as well as the QA/QC samples described in Section 5. The analytical methods for this sampling event are listed in Table 3.1. Prior to sampling, USEPA NRMRL personnel will provide a sufficient number of analyte-appropriate sample containers for the samples to be collected. All containers, preservatives, and shipping requirements will be consistent with USEPA protocol or those reported in Appendix A of this plan.

USEPA laboratory support personnel will specify the necessary QC samples and prepare appropriate QC sample bottles. For samples requiring chemical preservation, preservatives will be added to containers by the laboratory. Containers, ice chests with adequate padding, and cooling media will be provided by USEPA NRMRL laboratory personnel. Sampling personnel will fill the sample containers and return the samples to the field laboratory.

3.5 AQUIFER TESTING

Slug tests will be conducted in selected monitoring wells to estimate the hydraulic conductivity of unconsolidated deposits at the site. This information is required to accurately estimate the velocity of groundwater and contaminants in the shallow saturated zone. A slug test is a single-well hydraulic test used to determine the hydraulic conductivity of an aquifer in the immediate vicinity of the tested well. Slug tests can be used for both confined and unconfined aquifers that have a transmissivity

of less than 7,000 ft²/day. Slug testing can be performed using either a rising head or a falling head test; at this site, both methods will be used in sequence.

3.5.1 Definitions

- Hydraulic Conductivity (K). A quantitative measure of the ability of porous material to transmit water; defined as the volume of water that will flow through a unit cross-sectional area of porous or fractured material per unit time under a unit hydraulic gradient.
- Transmissivity (T). A quantitative measure of the ability of an aquifer to transmit water. It is the product of the hydraulic conductivity and the saturated thickness.
- Slug Test. Two types of testing are possible: rising head and falling head tests. A slug test consists of adding a slug of water or a solid cylinder of known volume to the well to be tested or removing a known volume of water or cylinder and measuring the rate of recovery of water level inside the well. The slug of a known volume acts to raise or lower the water level in the well.
- Rising Head Test. A test used in an individual well within the saturated zone to estimate the hydraulic conductivity of the surrounding formation by lowering the water level in the well and measuring the rate of recovery of the water level. The water level may be lowered by pumping, bailing, or removing a submerged slug from the well.
- Falling Head Test. A test used in an individual well to estimate the hydraulic conductivity of the surrounding formation by raising the water level in the well by insertion of a slug or quantity of water, and then measuring the rate of drop in the water level.

3.5.2 Equipment

The following equipment will be used to conduct a slug test:

- Teflon®, PVC, or metal slugs;
- Nylon or polypropylene rope;
- Electric water level indicator;
- Pressure transducer/sensor;
- Field logbook/forms; and
- Automatic data recording instrument (such as the Hermit Environmental DataLogger®, In-Situ, Inc. Model SE1000B, or equivalent).

3.5.3 General Test Methods

Aquifer hydraulic conductivity tests (slug tests) are accomplished by either removal of a slug or quantity of water (rising head) or introduction of a slug (falling head), and

then allowing the water level to stabilize while taking water level measurements at closely spaced time intervals.

Slug testing will proceed only after multiple water level measurements over time show that static water levels are in equilibrium. During the slug test, the water level change should be influenced only by the introduction (or removal) of the slug volume. Other factors, such as inadequate well development or extended pumping may lead to inaccurate results; in addition, slug tests will not be performed on wells with free product. The field scientist will determine when static equilibrium has been reached in the well. The pressure transducer, slugs, and any other downhole equipment will be decontaminated prior to and immediately after the performance of each slug test using the procedures described in Section 3.3.1.1.

3.5.4 Falling Head Test

The falling head test is the first step in the two-step slug testing procedure. The following steps describe procedures to be followed during performance of the falling head test.

- 1. Decontaminate all downhole equipment prior to initiating the test.
- 2. Open the well. Where wells are equipped with watertight caps, the well should be unsealed at least 24 hours prior to testing to allow the water level to stabilize. The protective casing should remain locked during this time to prevent vandalism.
- 3. Prepare the aquifer slug test data form (Figure 3.7) with entries for:
- · Borehole/well number,
- · Project number,
- · Project name,
- Aquifer testing team,
- · Climatic data,
- Ground surface elevation,
- Top of well casing elevation,
- Identification of measuring equipment being used,
- Page number,
- Static water level, and
- Date.
- 4. Measure the static water level in the well to the nearest 0.01 foot.

- 5. Lower the decontaminated pressure transducer into the well and allow the displaced water to return to its static level. This can be determined by periodic water level measurements until the static water level in the well is within 0.01 foot of the original static water level.
- 6. Lower the decontaminated slug into the well to just above the water level in the well.
- 7. Turn on the data logger and quickly lower the slug below the water table, being careful not to disturb the pressure transducer. Follow the owner's manual for proper operation of the data logger.
- 8. Terminate data recording when the water level stabilizes in the well. The well will be considered stabilized for termination purposes when it has recovered 80 to 90 percent from the initial displacement.

3.5.5 Rising Head Test

After completion of the falling head test, the rising head test will be performed. The following steps describe the rising head slug test procedure.

- 1. Measure the water level in the well to the nearest 0.01 foot to ensure that it has returned to the static water level.
- 2. Initiate data recording and quickly withdraw the slug from the well. Follow the owner's manual for proper operation of the data logger.
- 3. Terminate data recording when the water level stabilizes in the well, and remove the pressure transducer from the well and decontaminate. The well will be considered stabilized for termination purposes when it has recovered 80 to 90 percent from the initial displacement.

3.5.6 Slug Test Data Analysis

Data obtained during slug testing will be analyzed using AQTESOLVTM and the method of Bouwer and Rice (1976) and Bouwer (1989) for unconfined aquifer conditions.

SECTION 4

TS REPORT

Upon completion of field work and modeling, a TS report detailing the results of the investigation and subsequent modeling will be prepared. This report will follow the outline presented in Table 4.1. It will contain an introduction, a summary of physical characteristics, a discussion of the nature and extent of contamination (including geochemistry), a description of selected remedial alternatives, a groundwater model, and a proposed long-term monitoring plan.

QUALITY ASSURANCE/QUALITY CONTROL

Field QA/QC procedures will include collection of field replicates/duplicates and rinseate, field and trip blanks; decontamination of all equipment that contacts the sample medium before and after each use; use of analyte-appropriate containers; and chain-of-custody procedures for sample handling and tracking. All samples to be transferred to the analytical laboratory for analysis will be clearly labeled to indicate sample number, location, matrix (e.g., groundwater), and analyses requested. Samples will be preserved in accordance with the analytical methods to be used, and water sample containers will be packaged in coolers with ice to maintain a temperature of as close to 4°C as possible.

All field sampling activities will be recorded in a bound, sequentially paginated field notebook in permanent ink. All sample collection entries will include the date, time, sample locations and numbers, notations of field observations, and the sampler's name and signature. Field QC samples will be collected in accordance with the program described below, and as summarized in Table 5.1.

QA/QC sampling will include collection and analysis of duplicate groundwater and soil samples, rinseate blanks, field/trip blanks, and matrix spike samples. Internal laboratory QC analyses will involve the analysis of laboratory control samples (LCSs) and laboratory method blanks (LMBs). QA/QC objectives for each of these samples, blanks, and spikes are described below.

Soil and groundwater samples collected with the Geoprobe sampler should provide sufficient volume for some replicate and duplicate analyses. Refer to Table 3.1 and Appendix A for further details on sample volume requirements.

One rinseate sample will be collected for every 10 or fewer groundwater samples collected from existing wells. Rinseate samples will consist of a sample of distilled water poured into or pulled through decontaminated or new sampling equipment and subsequently transferred into a sample container provided by the laboratory. Rinseate samples will be analyzed for VOCs only.

A field blank will be collected for every 20 or fewer groundwater samples (both from groundwater monitoring point and groundwater monitoring well sampling events) to assess the effects of ambient conditions in the field. The field blank will consist of a sample of distilled water poured into a laboratory-supplied sample container while sampling activities are underway. The field blank will be analyzed for VOCs.

TABLE 5.1
QA/QC SAMPLING PROGRAM
FT-1 INTRINSIC REMEDIATION TS
FAIRCHILD AFB, WASHINGTON

QA/QC Sample Types	Frequency to be Collected and/or Analyzed	Analytical Methods
Duplicates/Replicates	4 Groundwater and 2 Soil Samples (10%)	VOCs, TPH
Rinseate Blanks	2 Samples (5% of Groundwater Samples)	VOCs
Field Blanks	2 Samples (5% of Groundwater Samples)	VOCs
Trip Blanks	One per shipping cooler containing VOC samples	VOCs
Matrix Spike Samples	Once per sampling event	VOCs
Laboratory Control Sample	Once per method per medium	Laboratory Control Charts (Method Specific)
Laboratory Method Blanks	Once per method per medium	Laboratory Control Charts (Method Specific)

A trip blank will be analyzed to assess the effects of ambient conditions on sampling results during the transportation of samples. The trip blank will be prepared by the laboratory. A trip blank will be transported inside each cooler which contains samples for VOC analysis. Trip blanks will be analyzed for VOCs.

Matrix spikes will be prepared in the laboratory and used to establish matrix effects for samples analyzed for VOCs.

LCSs and LMBs will be prepared internally by the laboratory and will be analyzed each day samples from the site are analyzed. Samples will be reanalyzed in cases where the LCS or LMB are out of the control limits. Control charts for LCSs and LMBs will be developed by the laboratory and monitored for the analytical methods used.

APPENDIX A

CONTAINERS, PRESERVATIVES, PACKAGING, AND SHIPPING REQUIREMENTS FOR GROUNDWATER SAMPLES

				Recommended Frequency of	Sample Volume,	Field or
ethod/	Method/Reference	Comments	Data Use	Analysis	Sample Preservation	Laboratory
Gas chromatograp mass spectrometry method SW8240.	Gas chromatography/ mass spectrometry method SW8240.	Handbook method	Data is used to determine the extent of chlorinated solvent and aromatic	Each sampling round	Collect 100 g of soil in a glass container with Teflon®-lined cap; cool	Fixed-base
			hydrocarbon contamination, contaminant mass present, and the need for source removal		to 4 °C	
Colorimetric RSKSOP-100		Reduction of added triphenyltetrazolium chloride by soil microbes is	An indicator of the presence of soil microbes, which are necessary for bioremediation to occur	At the beginning of the project	Collect 100 g of soil in a glass container	Field
		measured colorimetrically, analyze immediately				
Purge and trap gas	gas v (GC)	Handbook method	Data is used to determine the extent of soil	Each sampling round	Collect 100 g of soil in a glass container with	Fixed-base
method SW8020		extraction of soil using methanol	contamination, the contaminant mass present,		Teflon-lined cap; cool to 4°C	
			and the need for source removal			
GC method SW8015 [modified]	8015	Handbook method; reference is the	Data are used to determine the extent of soil	Each sampling round	Collect 100 g of soil in a glass container with Teffon lined care cool	Fixed-base
		Camotina LOF 1 manual	contamination, use contaminant mass present, and the need for source removal		to 4°C	

Field or Fixed-Base n Laboratory		Fixed-base		Field
Sample Volume, Sample Container, Sample Preservation	Collect 100 g of soil in a glass container with Teflon-lined cap; cool to 4°C	Use a portion of soil sample collected for another analysis	Collect 250 g of soil in a glass or plastic container, preservation is unnecessary	N/A
Recommended Frequency of Analysis	At initial sampling	Each soil sampling round	One time during life of project	Each sampling round
Data Use	Relatively high amounts of TOC may be indicative of a reducing environment and may indicate the need for analysis of electron acceptors associated with that environment; the rate of migration of petroleum contaminants in groundwater is dependent upon the amount of TOC in the saturated zone soil; the rate of release of petroleum contaminants from the acontaminants from the amount of TOC in the source into groundwater is dependent (in part) on the amount of TOC in the wadose zone soil	Data are used to correct soil sample analytical results for moisture content (e.g., report results on a dry weight basis)	Data are used to infer hydraulic conductivity of aquifer, and are used in calculating sorption of contaminants	Data used to understand the carbon dioxide concentration gradient with depth and to infer the biological degradation of
Comments	Procedure must be accurate over the range of 0.5– 15 percent TOC	Handbook method	Procedure provides a distribution of grain size by sieving	Soil gas carbon dioxide may be produced by the degradation of petroleum
Method/Reference	Sw9060 modified for soil samples	ASTM D-2216	ASTM D422	Nondispersive infrared instrument operating over the range of approximately 0.1—15 percent

Field or Fixed-Base Laboratory	Fixed-base
Sample Volume, Sample Container, Sample Preservation	Collect water samples in 40 mL volatile organic analysis (VOA) vials with butyl gray/Teflon-lined caps; cool to 4°C
Recommended Frequency of Analysis	Each sampling round
Data Use	The presence of methane suggests BTEX degradation via an anaerobic pathway utilizing carbon dioxide (carbonate) as the electron acceptor (methanogenesis); a redox potential measurement of less than -200 mV could be indicative of methanogenesis and should be followed by the analysis referenced here; the presence of free carbon dioxide dissolved in groundwater is unlikely because of the carbonate buffering system of water, but if detected, the carbon dioxide concentrations should be compared with background to determine whether they are elevated; elevated concentrations of carbon dioxide concentrations of carbon dioxide concentrations of carbon dioxide concentrations of carbon dioxide could midicate an aerobic mechanism for bacterial degradation of petroleum
Comments	Method published and used by the U.S. Environmental Protection Agency (EPA) Robert S. Kerr Laboratory
Method/Reference	RSKSOP-114 modified to analyze water samples for methane and carbon dioxide by headspace sampling with dual thermal conductivity and flame ionization detection (also, see reference in note 10)
Analysis	Methane, carbon dioxide.
Matrix	Water

me, Field or ainer, Fixed-Base ervation Laboratory	samples Fixed-base OA vial; dd dd to	ocarbons- Fixed-base samples OA vial; dd acid to -collect n a glass ol to 4°C; vric acid to	water in Fixed-base ner; cool
Sample Volume, Sample Container, Sample Preservation	Collect water samples in a 40 mL VOA vial; cool to 4°C; add hydrochloric acid to pH 2	Volatile hydrocarbons-collect water samples in a 40 mL VOA vial; cool to 4°C; add hydrochloric acid to pH 2 Extractable hydrocarbons-collect 1 L of water in a glass container; cool to 4°C; add hydrochloric acid to pH 2	Collect 1 L of water in a glass container, cool to 4°C
Recommended Frequency of Analysis	Each sampling round	One time per year or as required by regulations	At mitial sampling and at site closure or as required by regulations
Data Use	Method of analysis for BTEX, which is the primary target analyte for monitoring natural attenuation; BTEX concentrations must also be measured for regulatory compliance, method can be extended to higher molecular weight alkyl benzenes; trimethylbenzenes are used to monitor plume dilution if degradation is primarily anaerobic	Data used to monitor the reduction in concentrations of total fuel hydrocarbons (in addition to BTEX) due to natural attenuation; data also used to infer presence of an emulsion or surface layer of petroleum in water sample, as a result of sampling	PAHs are components of fuel and are typically analyzed for regulatory compliance, data on their concentrations are not used currently in the evaluation
Comments	Handbook method; analysis may be extended to higher molecular weight alkyl benzenes	Handbook method; reference is the California LUFT manual	Analysis needed only for several samples per site
Method/Reference	Purge and trap GC method SW8020	GC method SW8015 [modified]	GC/mass spectroscopy method SW8270; high-performance liquid chromatography method SW8310
Analysis	Aromatic hydrocarbons (BTEX, trimethylbenzene isomers)	Total hydrocarbons, volatile and extractable	Polycyclic aromatic hydrocarbons (PAHs) (optional)
Matrix	Water	Water	Water

Field or Fixed-Base Laboratory	Fixed-base	Fixed-base	Fixed-base
Sample Volume, Sample Container, Sample Preservation	Collect 40 mL of water in glass vials with Teflon-lined caps; add sulfuric acid to pH 2; cool to 4°C	Collect water samples in a 40 mL VOA vial; cool to 4°C; add hydrochloric acid to pH 2	Collect 100 mL of water in an amber glass container with Teflon-lined cap, preserve with sulfuric acid to pH less than 2, cool to 4°C. Collect 100–250 mL of water in a glass or plastic container,
Recommended Frequency of Analysis	At initial sampling and at site closure	Each sampling round	Each sampling round Each sampling round
Data Use	Data used to monitor the reduction in concentrations of total fuel hydrocarbons (in addition to BTEX) due to natural attenuation	Method of analysis for chlorinated solvents and aromatic hydrocarbons for evaluation of cometabolic degradation; measured for regulatory compliance when chlorinated solvents are known site	An indirect index of microbial activity Aerobic and anaerobic processes are pH-sensitive
Comments	A substitute method for measuring total volatile hydrocarbons; reports amount of fuel as carbon present in the sample; method available from the U.S. EPA Robert S. Kert Laboratory	Handbook method	An oxidation procedure whereby carbon dioxide formed from DOC is measured by an infrared spectrometer. The minimum detectable amount of DOC is 0.05 mg/L Protocols/Handbook methods
Method/Reference	Purge and trap GC method SW8020 modified to measure all volatile aromatic hydrocarbons present in the sample	GS/MS method SW8240	A5310 C E150.1/SW9040, direct reading meter
